## UNIT-7

### Data Flow Analysis

- ✓ Flow graph
- ✓ Data flow equation
- ✓ Global Optimization
- ✓ Redundant Sub expression elimination
- ✓ Induction Variable elimination
- ✓ Live variable Analysis
- ✓ Copy propagation.

Flow graph :-

A flow graph is a directed graph in which the flow control information is added to the basic block.

- The nodes to the flow graph are represented by basic blocks.
- The basic block whose leader is the first statement is called initial block.
- There is a directed edge from block  $B_1$  to block  $B_2$ . If  $B_2$  immediately follows  $B_1$ . In the given sequence, you can say that  $B_1$  is a predecessor of  $B_2$ .

For example:- Consider 3-address code for

```
    Begin
        PROD:=0
        I:=1
        do begin
            PROD:= PROD+A[I]*B[I];
            I:= I+1
        END
    while I<=20
    END.
```

Sol The 3-address code is

- 1) PROD:=0
- 2) I:=1
- 3) loop : = t, := 4\*I;

- 4)  $t_2 := A[t_1]$
  - 5)  $t_3 := 4 * i$
  - 6)  $t_4 := B[t_3]$
  - 7)  $t_5 := t_2 * t_4$
  - 8)  $t_6 := \text{PROD} + t_5$
  - 9)  $\text{PROD} := t_6$
  - 10)  $t_7 := i + 1$
  - 11)  $i = t_7$
  - 12)  $i <= 20 \text{ goto loop 3.}$

The flow graph for the above code can be drawn as follows

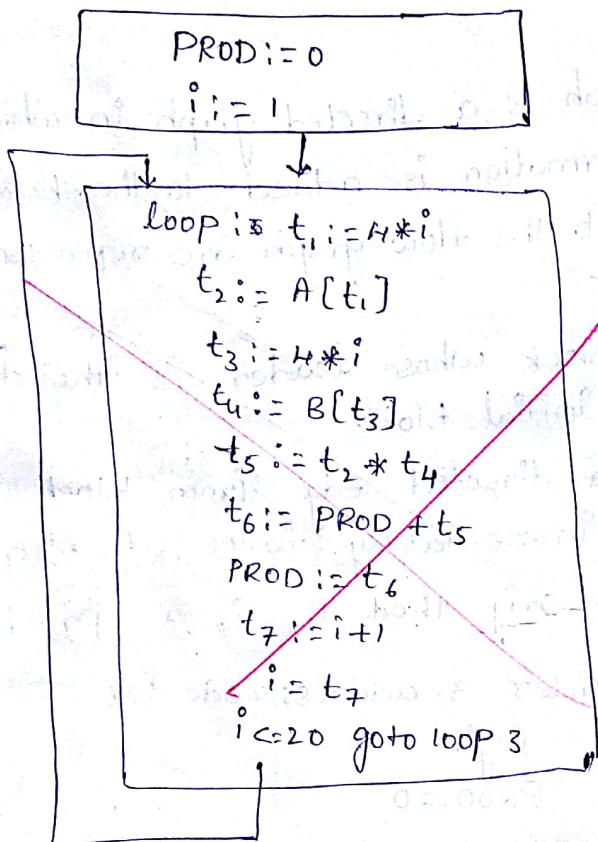

fig: flow graph

In the above flow graph, we have 2 basic blocks  $B_1$  &  $B_2$ .

Here  $B_1$ , Basic block is a initial block & it transmit the data to the basic block  $B_2$ .

→ Loops in flow graph :-

→ Loops in flow graph.  
Let us get introduced with some common technologies being used for loop in flow graph.

## 1) Dominator:

In a flow graph a node 'd' dominates 'n' if every path to node 'n' from initial node goes through 'd'. This can be denoted as  $d \text{ dom } n$ .

Every initial node dominates all the remaining nodes in the flow graph. Similarly every node dominates its self.

Eg:-

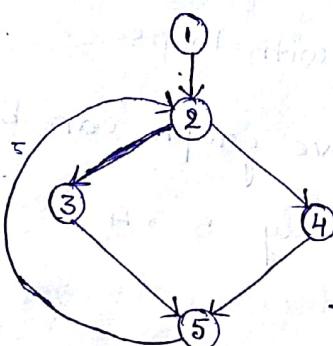

fig: flow graph

In above flow graph, node 1 is initial node & it dominates every node as it is a initial node.

→ Node 2 dominates 3, 4, & 5 as there exist only one path from initial node to node 2 which is going through  $2(1-2-3)$  similarly for node 4 only path exist is  $1-2-4$  and for node 5 the only path existing  $1-2-3-5$  (or)  $1-2-3-4$  which is going through the node 2.

→ Node 3 dominates itself similarly node 4 dominates itself the reason is that for going to remaining node 5, node 5 dominates no node.

## 2) Natural loops:-

Loop in a flow graph can be denoted by  $n \rightarrow d$  such that " $d \text{ dom } n$ " these edges are called back edges and for a loop there can be more than one back edges. If there is  $p \rightarrow q$  then  $q$  is head &  $p$  is tail & head dominates tail.

Eg:-

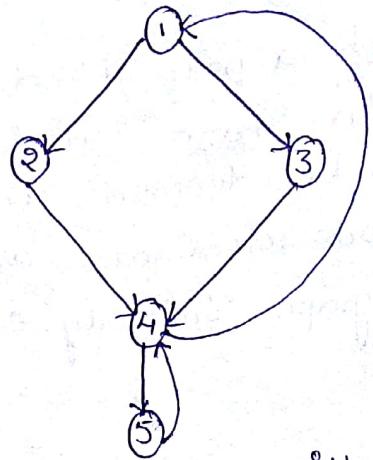

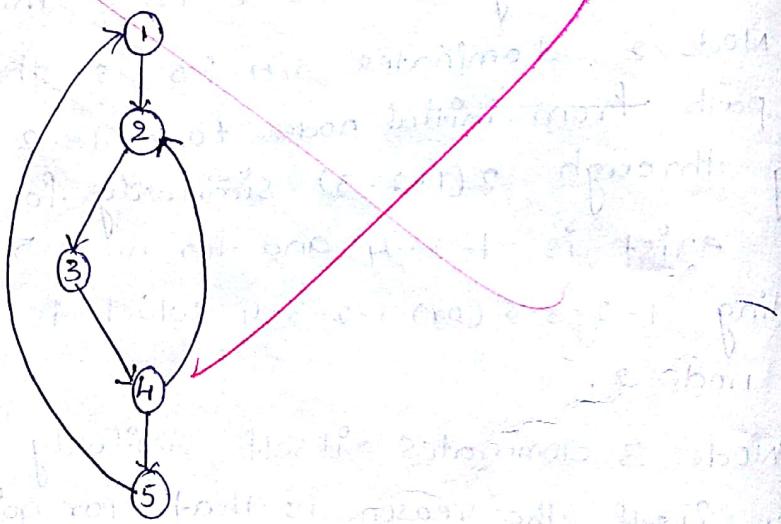

fig: flow graph with loops

The loops in the above graph can be denoted by  
 $4 \rightarrow 1$  i.e. 1 dom 4. Similarly  $5 \rightarrow 4$  i.e., 4 doms

### 3) Inner loops:

The inner loop is a loop that contains no other loop.

Eg:-

Here the inner loop is  $4 \rightarrow 3 \rightarrow 2$  i.e. edge given by 2-3-4.

### 4) Reducible flow graph:

The reducible flow graph is a flow graph in which there are two types of edges i.e., forward edges & backward edges. These edges have following properties.

1. The forward edge from an acyclic graph
2. The backward edges are such edges whose head dominates their tail.

Eg:-

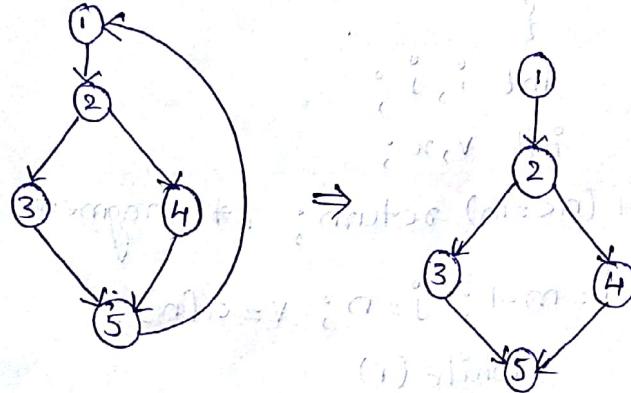

Fig: flow graph

The above flow graph is reducible. we can reduce this graph by removing the back edge from 3 to 2 . Similarly by removing the back edge from 5 to 1 .

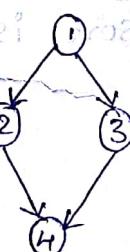

### 5) Non Reducible flow graph:-

A non-reducible flow graph is a flow graph which is a flow graph in which

1. There are no back edges

2. Forward edges may produce cycle in the graph.

Eg:-

Ques. Draw the flow graph by using quick sort(c code).

void quick sort (m,n)

int m,n;

{

int i,j;

int v,x;

if ( $n \leq m$ ) return; /\* fragment begins here,

i = m-1; j = n; v = a[n];

while (i)

{

do

i = i+1; while ( $a[i] < v$ );

do

j = j-1; while ( $a[j] > v$ );

if ( $i \geq j$ ) break;

x = a[i]; a[i] = a[j] > v;

2

x = a[i]; a[i] = a[n]; a[j] = x;

/\* fragment begins

here \*/

quick sort (m, j); quick sort (j+1, n);

Sol The 3-address code for quick sort is as follows.

1.  $i := m-1$

2.  $j := n$

3.  $t_1 := 4 * n$

4.  $v := a[t_1]$

5.  $i := i + 1$

6.  $t_2 := 4 * i$

7.  $t_3 := a[t_2]$

8.  $t_3 < v$  goto step 5

9.  $j = j - 1$

10.  $t_4 := 4 * j$

11.  $t_5 := a[t_4]$

12.  $t_5 > v$  goto step 9

13. if  $i >= j$  goto 23

14.  $t_6 := 4 * i$

15.  $x := a[t_6]$

16.  $t_7 := 4 * i$

17.  $t_8 := 4 * j$

18.  $t_9 := a[t_8]$

19.  $a[t_7] := t_9$

20.  $a[t_9] <= t_9$

21.  $t_{10} := 4 * j$

22. goto step 5

23.  $t_{11} := 4 * i$

24.  $x := a[t_{11}]$

25.  $t_{12} := 4 * i$

26.  $t_{13} := 4 * n$

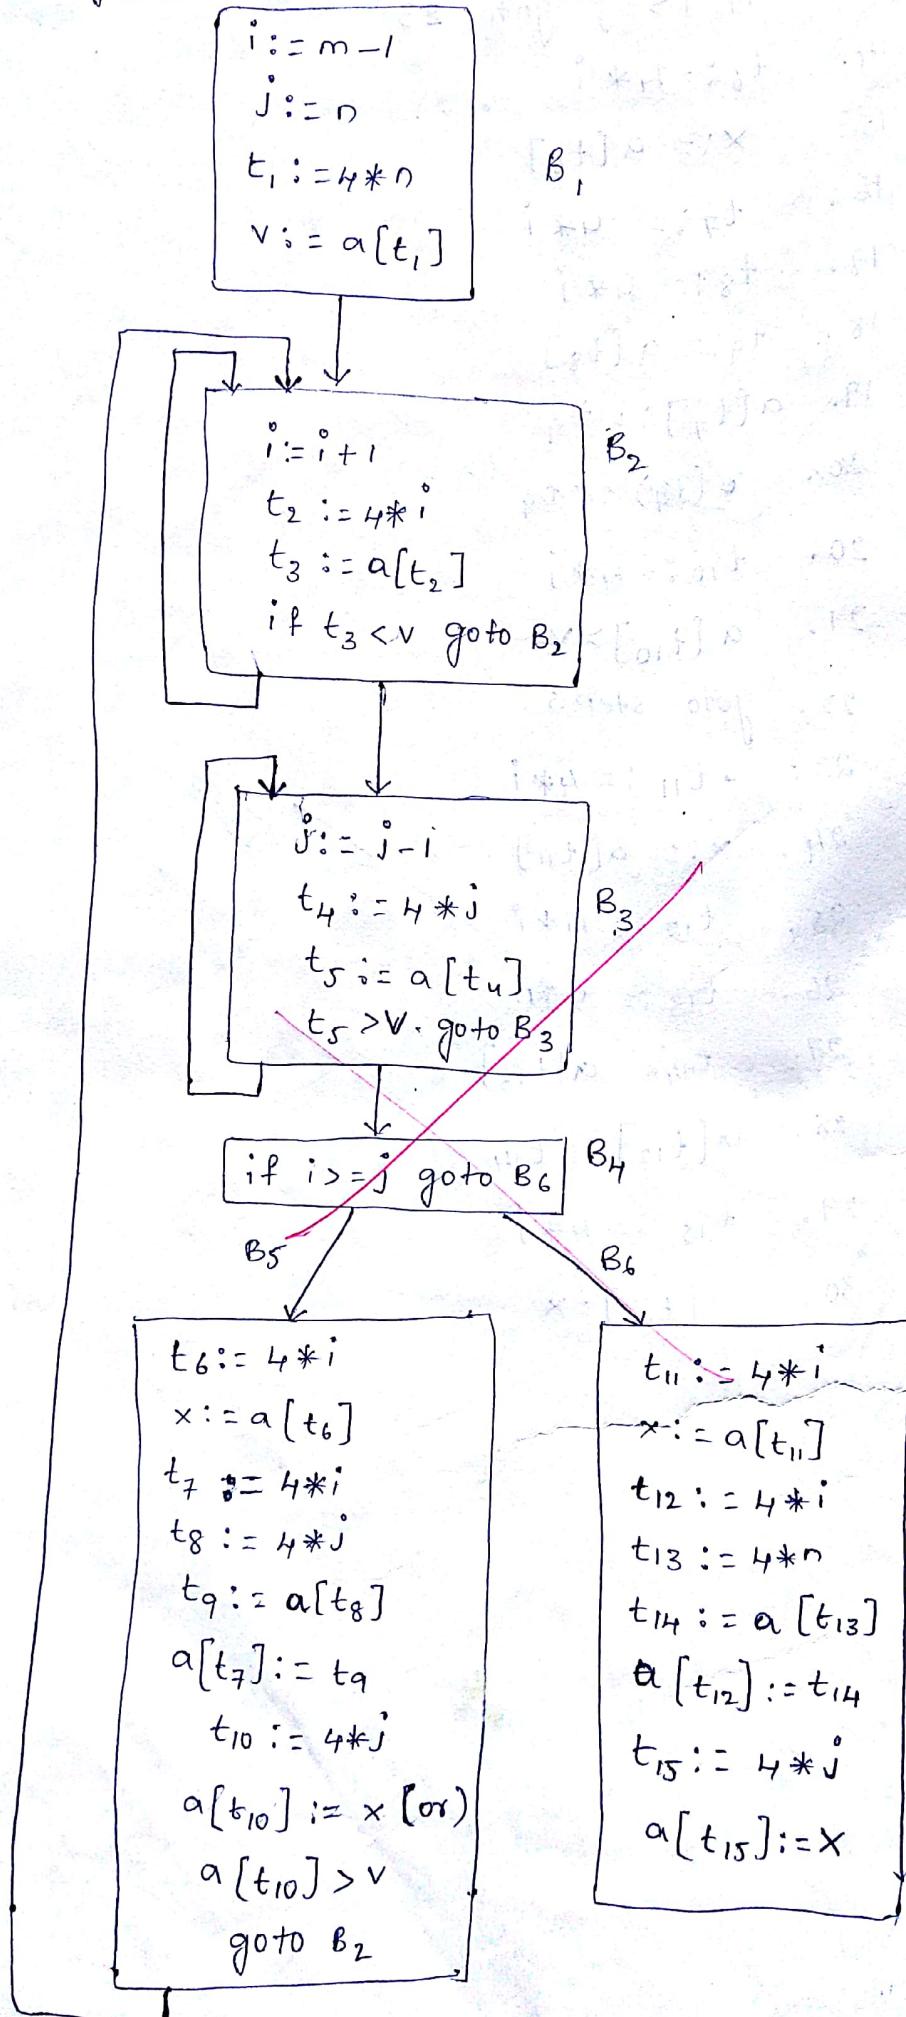

27.  $t_{14} := a[t_{13}]$

28.  $a[t_{12}] := t_{14}$

29.  $t_{15} := 4 * j$

30.  $a[t_{15}] = x$

## Flow graph:-

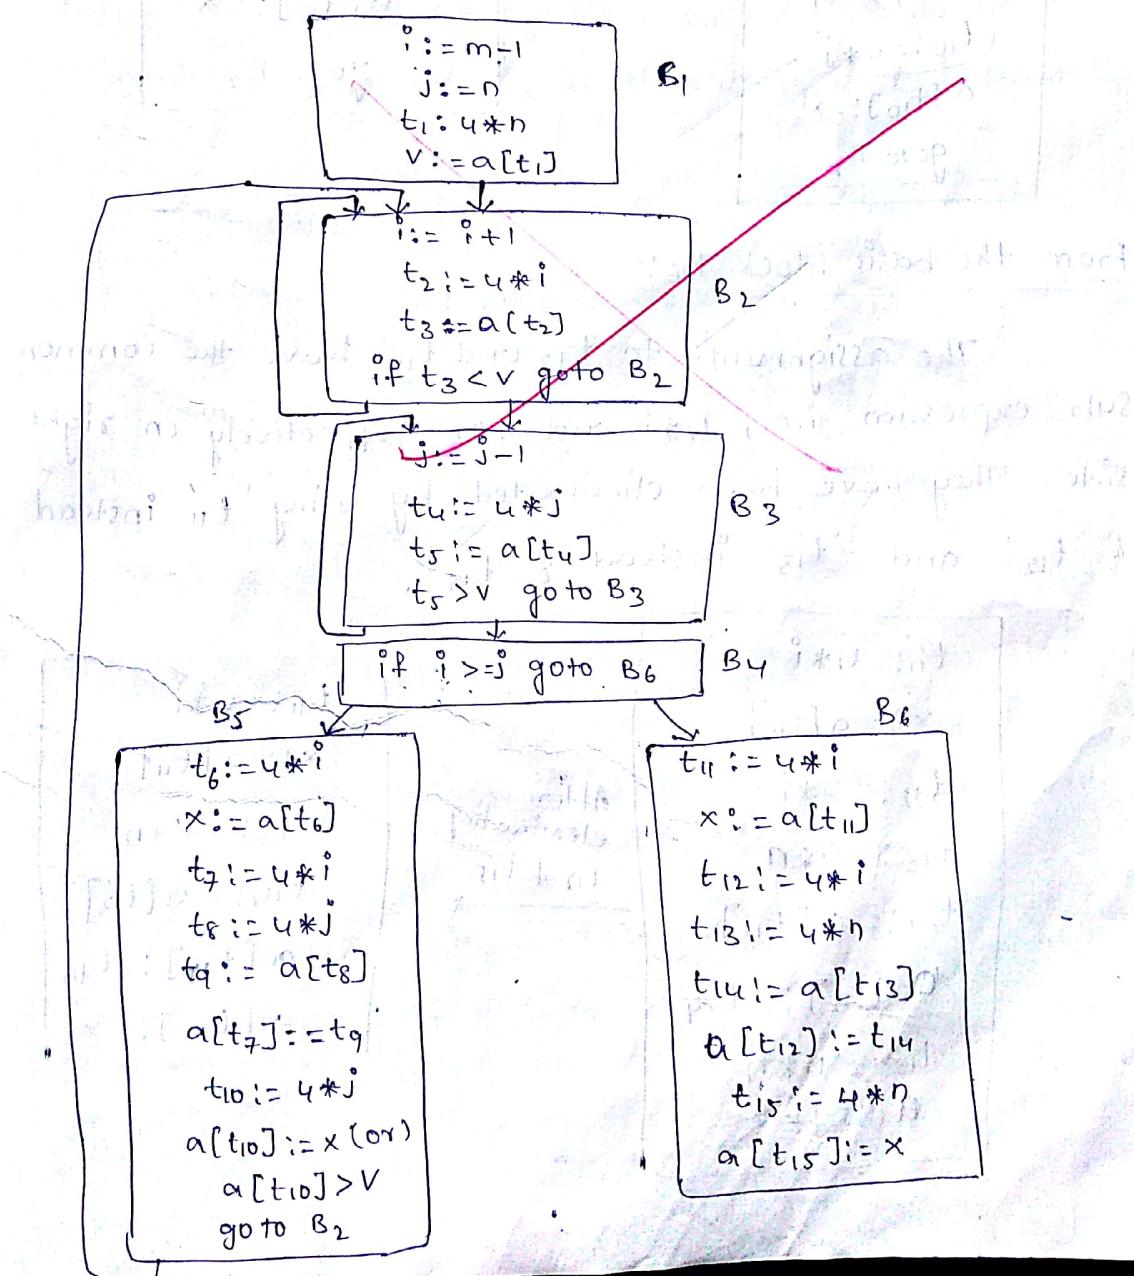

Local optimization (or) Function preserving Transformations

Here we mainly concentrate on

- 1) redundant common sub expression elimination.
- 2) copy propagation.
- 3) Dead code elimination.
- 4) Constant folding

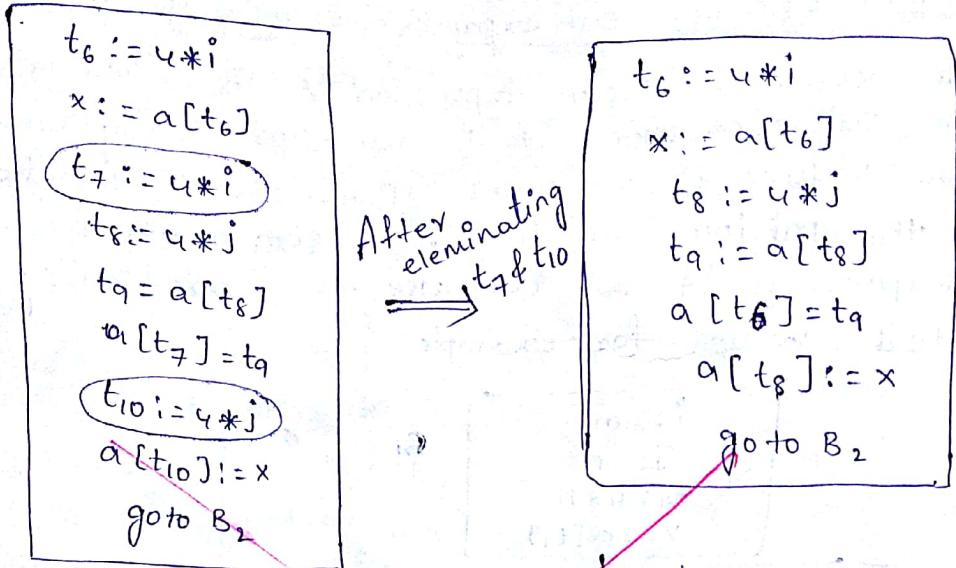

Redundant common sub expression elimination:-

An occurrence of an expression 'E' is called a common sub expression if 'E' was previously computed and the values of variables in 'E' have not changed since the previous computation. We can avoid recomputing the expression if we can use the previously computed value. For example

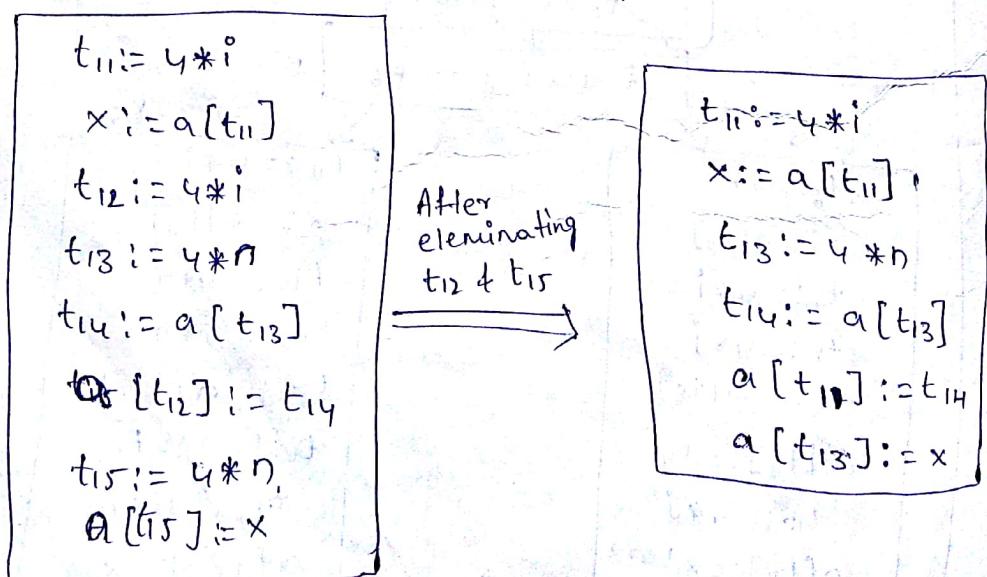

From the basic block  $B_5$  :-

The assignment to  $t_7$  and  $t_{10}$  have the common sub expression i.e.,  $4*i$  and  $4*j$  respectively from on right side. They have been eliminated by using ' $t_6$ ' instead of ' $t_7$ ' and ' $t_8$ ' instead of ' $t_{10}$ '.

From the basic block  $B_6$  :-

The assignments to  $t_{12}$  and  $t_{15}$  have the common sub expression i.e.,  $4*i$  and  $4*n$  respectively on right side. They have been eliminated by using ' $t_{11}$ ' instead of ' $t_{12}$ ' and ' $t_{13}$ ' instead of ' $t_{15}$ '.

→ After local common subexpressions are eliminated, B<sub>5</sub> still evaluates  $4*i + 4*j$ . They have been eliminated by using  $t_2$  instead of  $t_6 + t_4$  instead of  $t_8$ .

→ After eliminating  $t_6$  and  $t_8$  the basic block B<sub>5</sub> can be written as

```

 $t_6 := 4*i$ 
x := a[t6]
 $t_8 := 4*j$ 
t9 := a[t8]
a[t6] := t9
a[t8] := x
goto B2

```

After eliminating  
 $t_6 + t_8$

```

x := a[t2]
t9 := a[t4]
a[t2] := t9
a[t4] := x
goto B2

```

The common sub expression  $t_{11} + t_{13}$  have been eliminated by using  $t_2$  instead of  $t_{11} + t_1$  instead of  $t_{13}$

```

 $t_{11} := 4*i$ 
x := a[t11]
 $t_{13} := 4*j$ 
t14 := a[t13]
a[t11] := t14
a[t13] := x
goto B2

```

After eliminating  
 $t_{11} + t_{13}$

```

x := a[t2]
t14 := a[t1]
a[t2] := t14
a[t1] := x

```

B<sub>5</sub> & B<sub>6</sub> still have common sub expressions  $a[t_i]$  and may not have the same value on reaching B<sub>6</sub> and it is not safe to treat  $a[t_i]$  as a common sub expression.

→ The common sub expression  $t_9$  has been eliminated by using  $t_5$  instead  $t_9$

```

x := a[t2]
 $t_9 := a[t_4]$ 
a[t2] := t5
a[t4] := x
goto B2

```

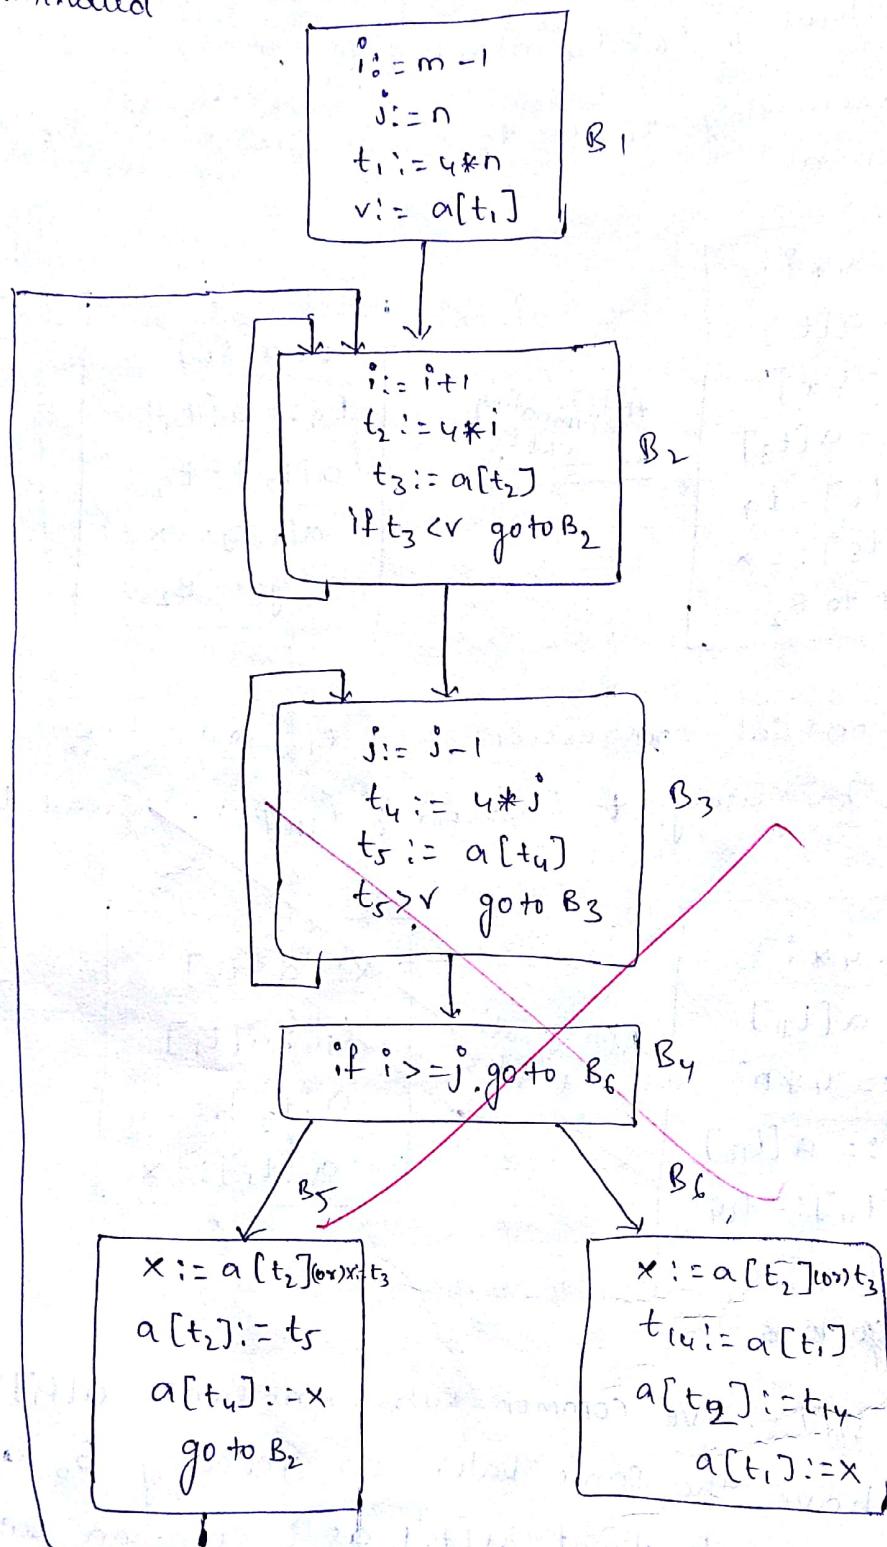

$t_9$

```

x := a[t2]
a[t2] := t5
a[t4] := x
goto B2

```

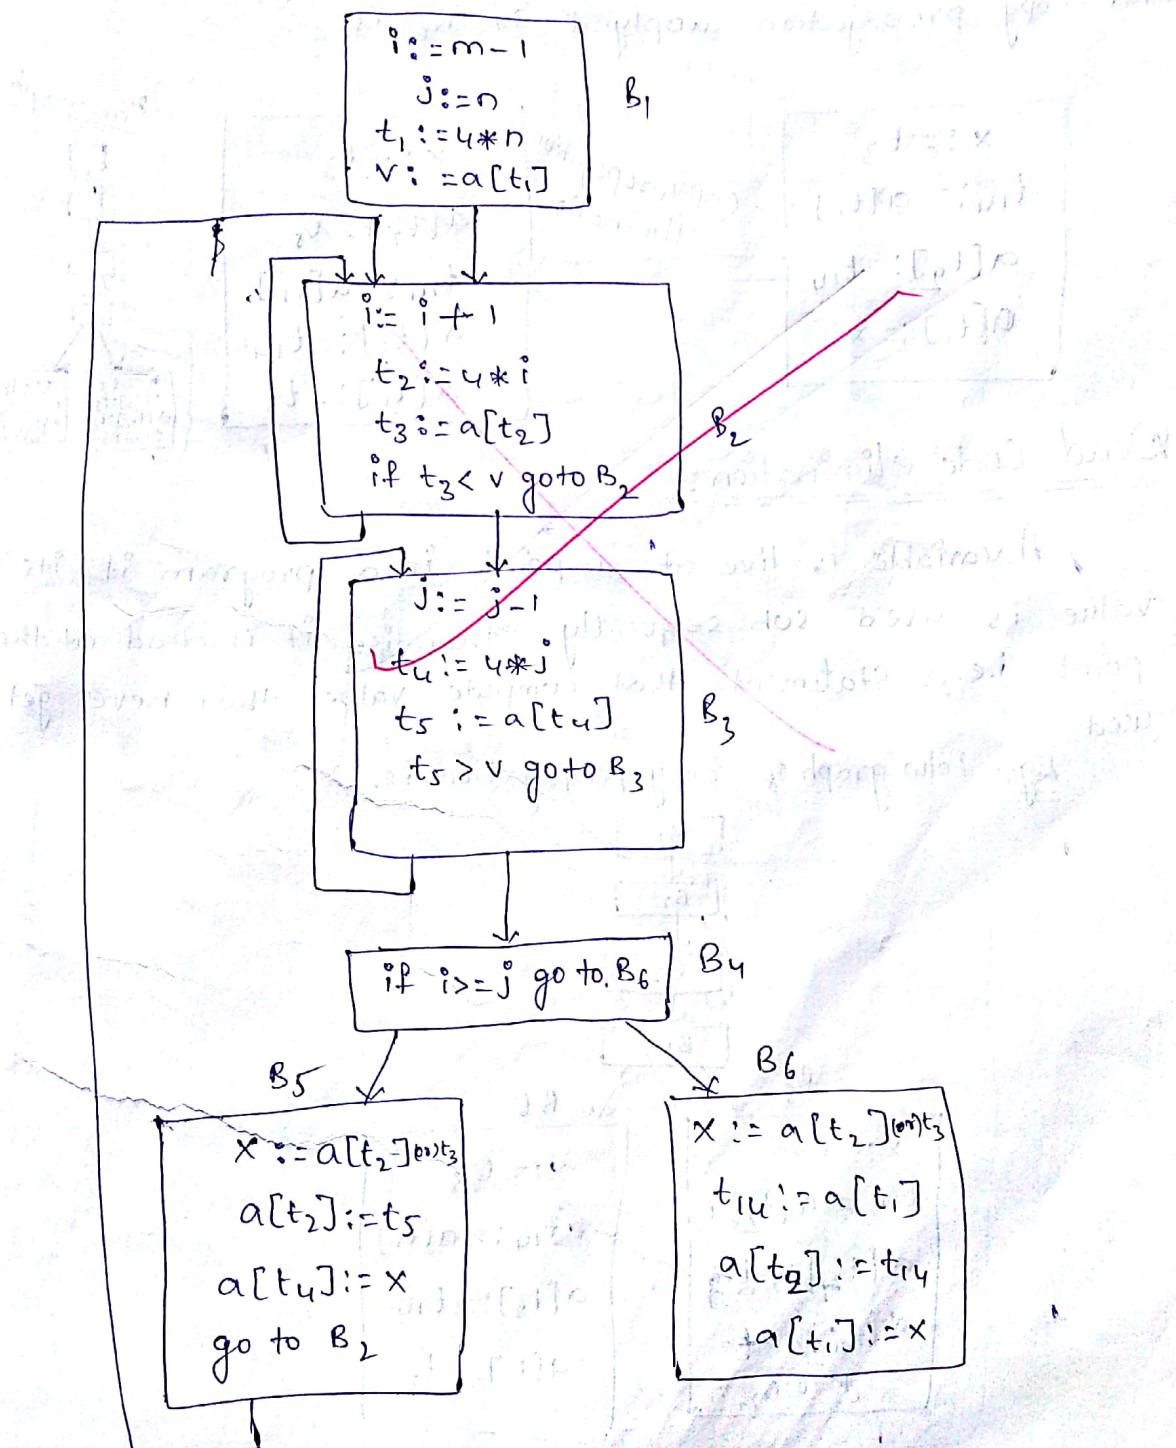

The flow graph after common sub expressions are eliminated

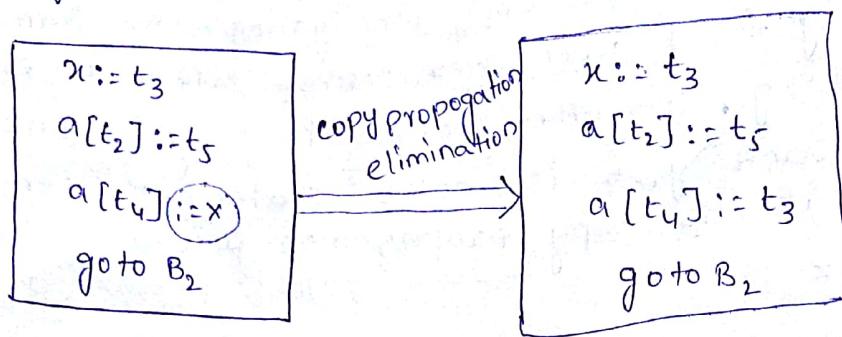

## Copy Propagation :-

The form  $f := g$  called copy statements (or) copies the idea behind the copy propagation transformation is to use  $g$  for  $f$  whenever possible after the copy statement  $f := g$ . In other words if  $x := y$  is one statement and  $y := z$  is another statement then if and Only if the copy propagation can be written as  $x := z$ .

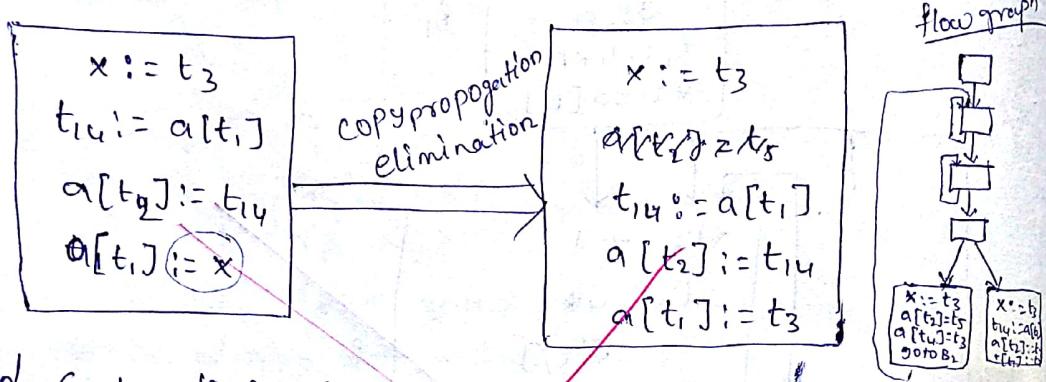

Eg:- Consider the flow graph after elimination of common sub expression is

The assignment  $x := t_3$  in block  $B_5$  is a copy statement  
and copy propagation applied to  $B_5$  is

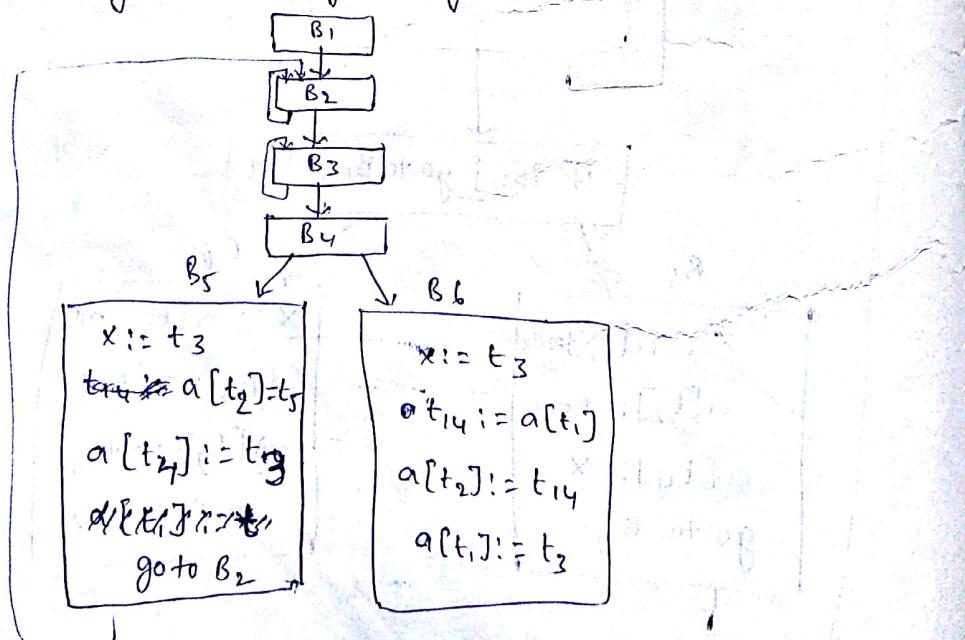

The assignment  $x := t_3$  in block  $B_6$  is a copy statement  
and copy propagation applied to  $B_6$  is

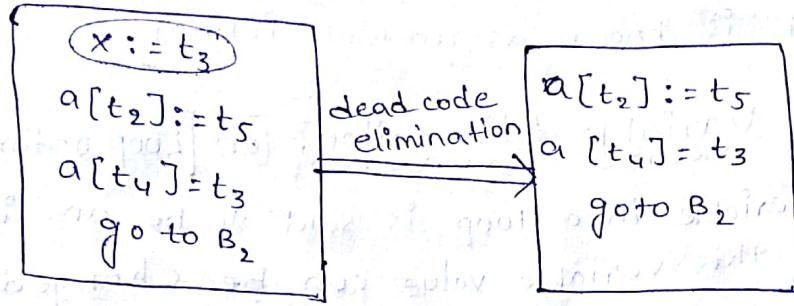

### Dead Code elimination :-

A variable is live at a point in a program if its value is used subsequently. Otherwise it is dead at the point. i.e., statements that compute values that never get used

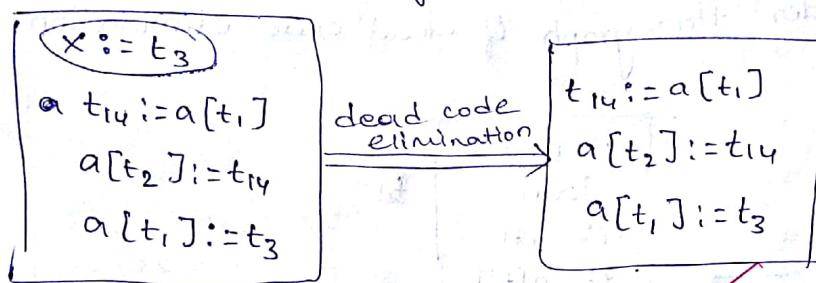

Eg:- Flow graph of copy propagation is.

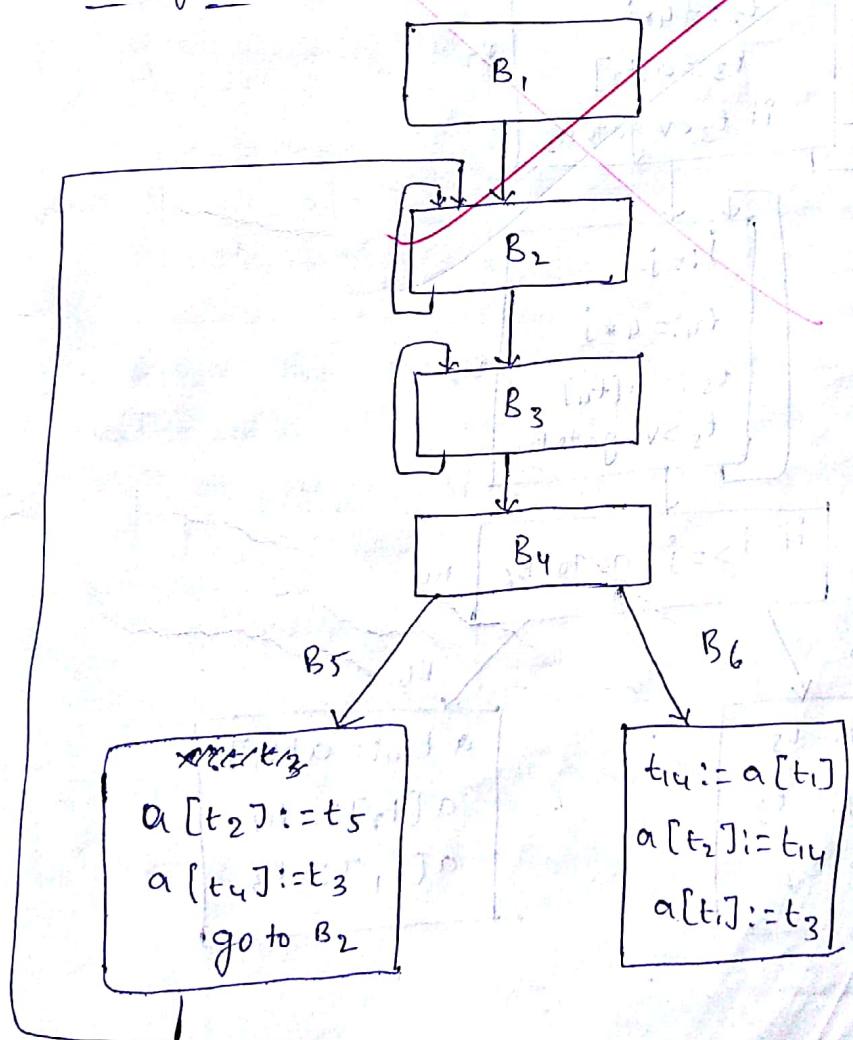

The assignments  $x := t_3$  in Block  $B_5$  is a dead code. Dead code elimination is applied to  $B_5$  is

The assignments  $x := t_3$  in Block  $B_6$  is a dead code. Dead code elimination is applied to  $B_6$  is

Flow graph:-

## Constant folding :-

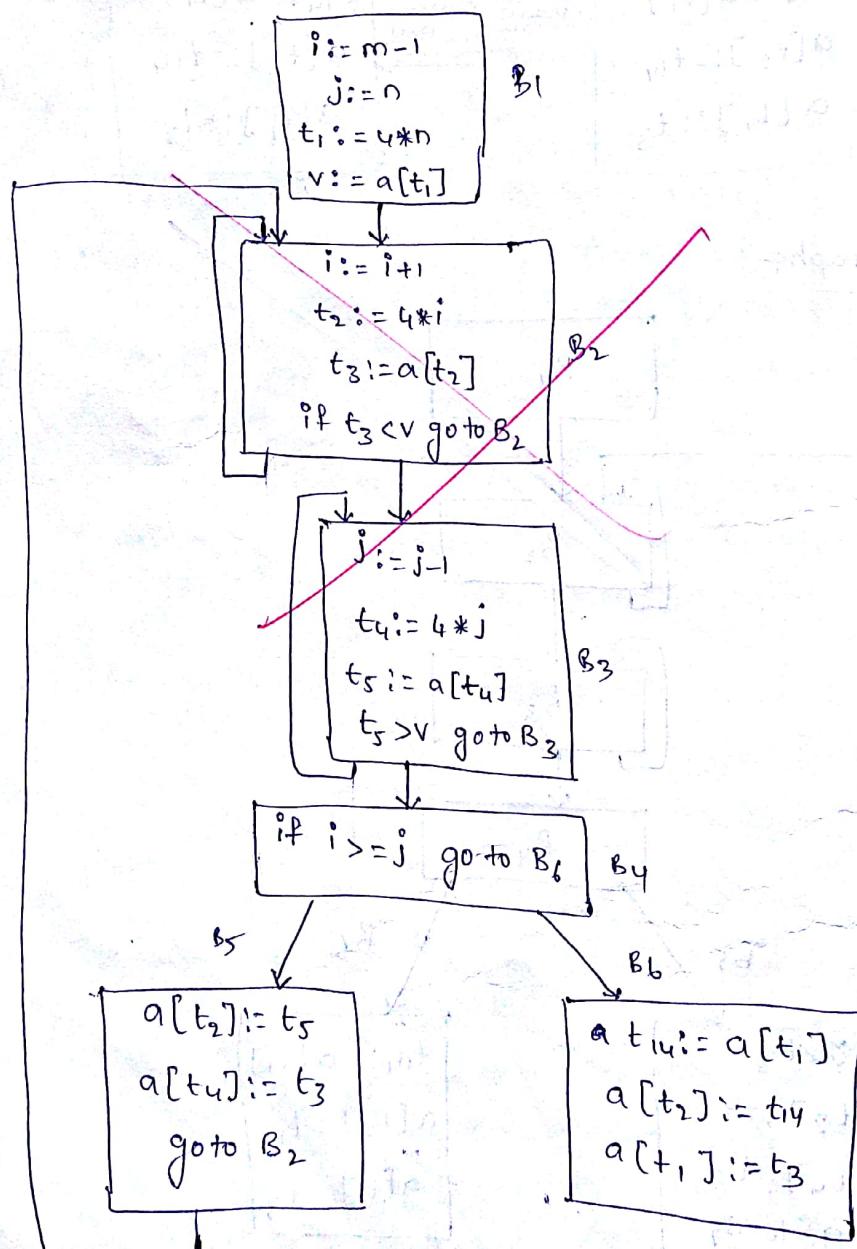

The substitution of values for names whose values are constant is known as constant folding.

\* \* \* Smp

## Induction Variable Elimination:- (01) [Loop optimization]

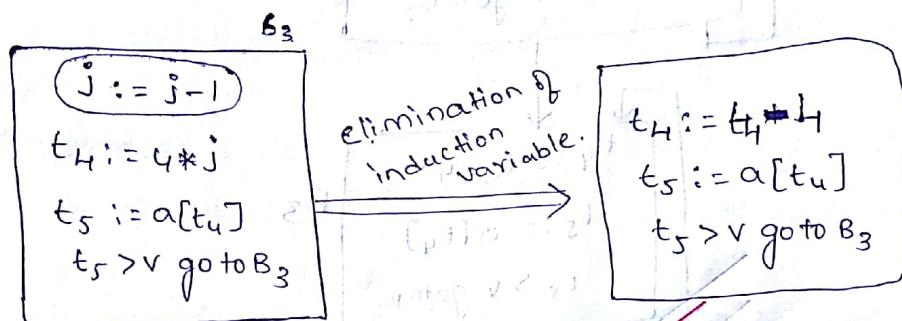

A variable in a loop is said to be an induction variable, if this variable value can be changed by using some constant. Here, changing of the variable is may be increment (or) decrement.

Eg:- Consider flow graph of dead code elimination. is

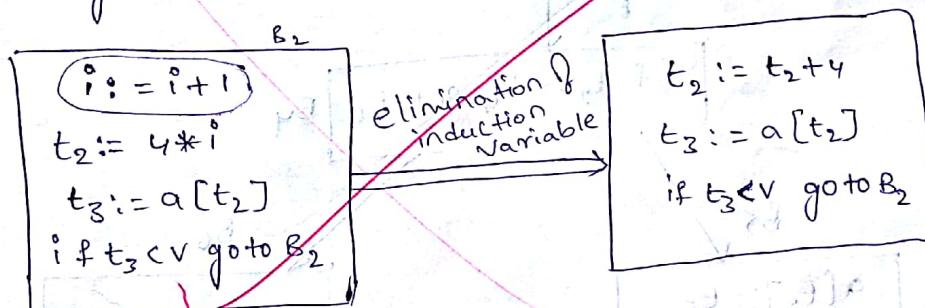

The values of  $j$  and  $t_4$ , every time the value of ' $j$ ' decreases by one, that of  $t_4$  decreases by 4 because of  $4*j$  is assigned to  $t_4$ . Therefore, replace the assignment  $t_4 = 4*j$  by  $t_4 = t_4 - 4$ .

The only problem is that  $t_4$  does not have a value when we enter block  $B_3$  for the first time since we must maintain the relationship  $t_4 = 4*j$  on entry to the block  $B_3$ , we place an initialization of  $t_4$  at the end of block where ' $j$ ' it self is initialized.

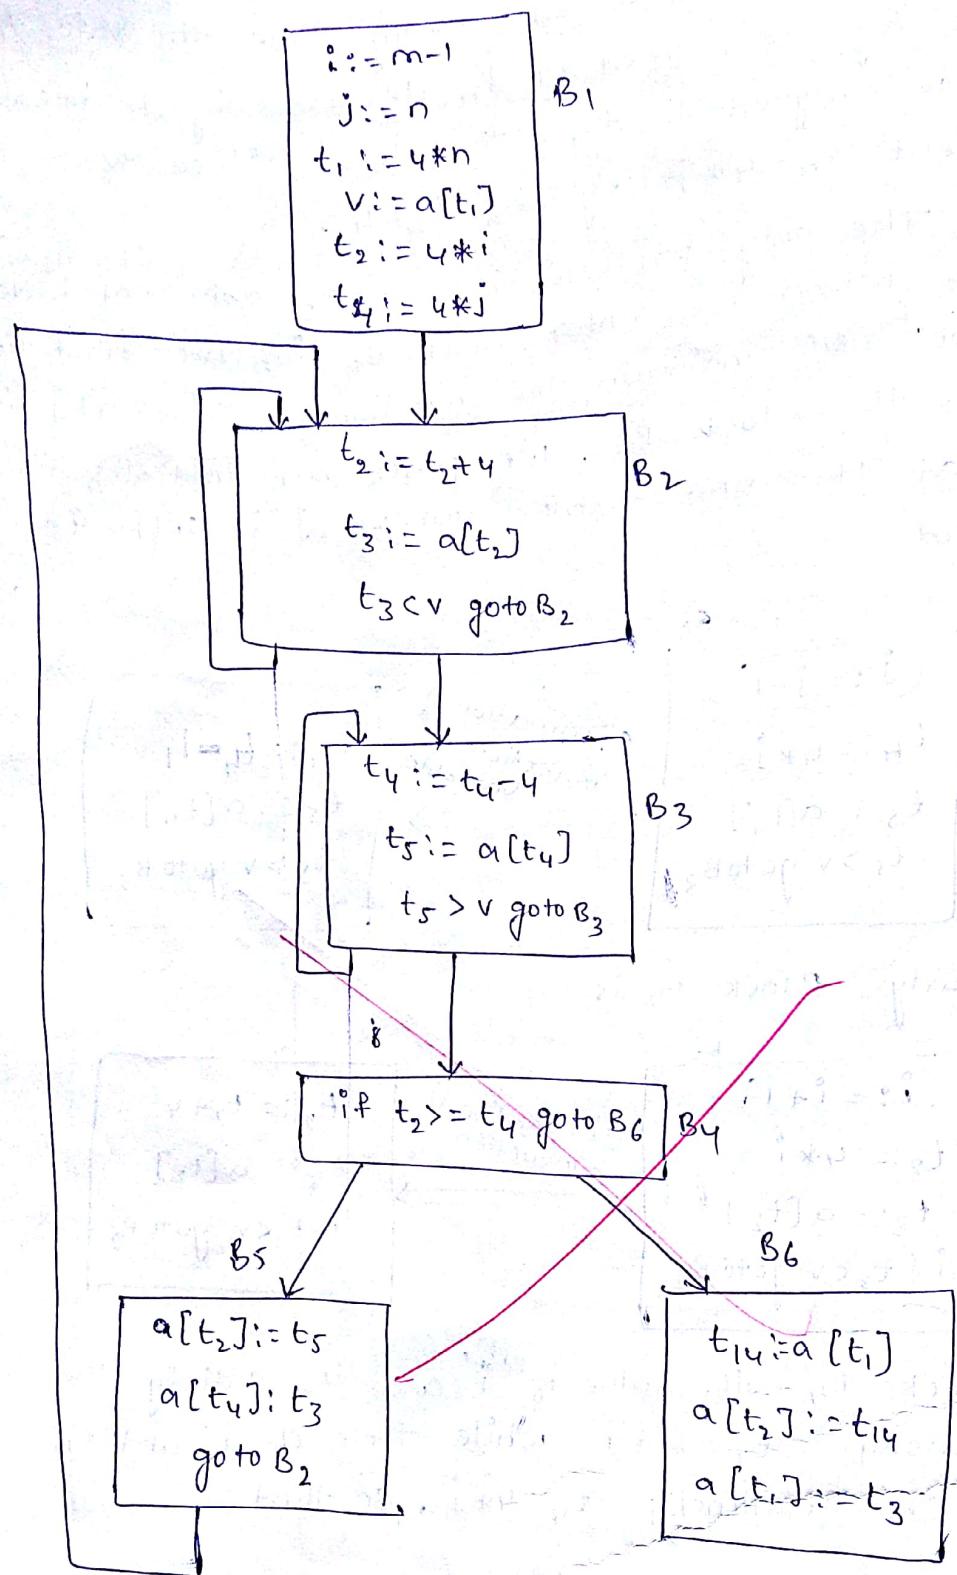

Similarly Block  $B_2$  is

In block  $B_4$  the value of ' $i$ ' and  $t_2$  satisfy the relationship  $t_2 = 4*i$ , while those of ' $j$ ' and  $t_4$  satisfy the relationship  $t_4 = 4*j$ , so that

∴ The required flow graph of induction variable elimination is.

Note :-

1) Explain about the principle sources of optimization (or)

2) Explain about local optimization & loop optimization

- \* Write 1) 3-address code  
 2) Basic block  
 3) flow graph  
 4) elimination of common sub-expression

```

begin
PROD = 0
i := 1
do
begin
    PROD := PROD + A[i] * B[i]
    i := i + 1
END
while i <= 20
END.
    
```

### Sol 1) 3-address code

- 1) PROD := 0
- 2) i := 1
- 3) loop:  $t_1 := 4 * i$
- 4)  $t_2 := A[t_1]$
- 5)  $t_3 := 4 * i$
- 6)  $t_4 := B[t_3]$
- 7)  $t_5 := t_2 * t_4$
- 8)  $t_6 := PROD + t_5$
- 9) PROD :=  $t_6$
- 10)  $t_7 := i + 1$
- 11)  $i := t_7$
- 12)  $i \leq 20$  goto loop ③

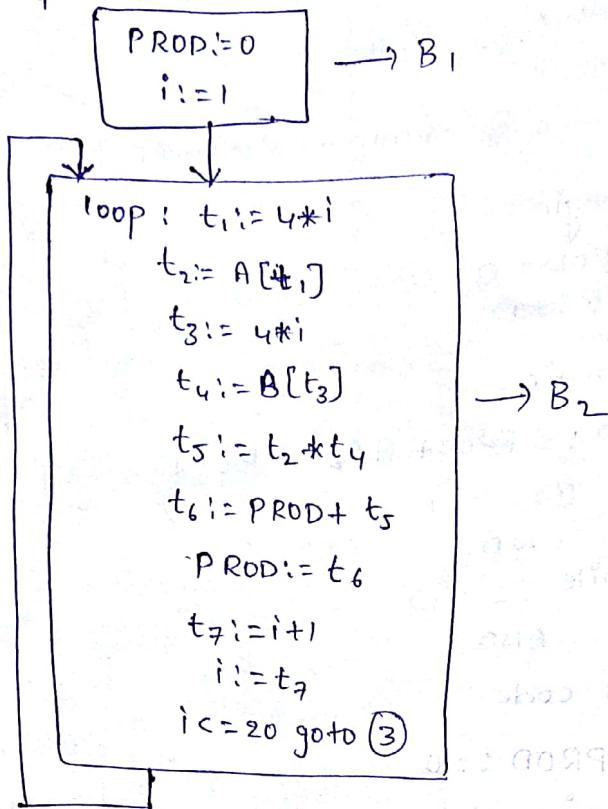

2)

PROD := 0	B <sub>1</sub>
i := 0	

loop : $t_1 := 4 * i$	
$t_2 := A[t_1]$	
$t_3 := 4 * i$	
$t_4 := B[t_3]$	
$t_5 := t_2 * t_4$	
$t_6 := PROD + t_5$	
PROD := $t_6$	
$t_7 := i + 1$	
$i := t_7$	
$i \leq 20$ go to loop ③	

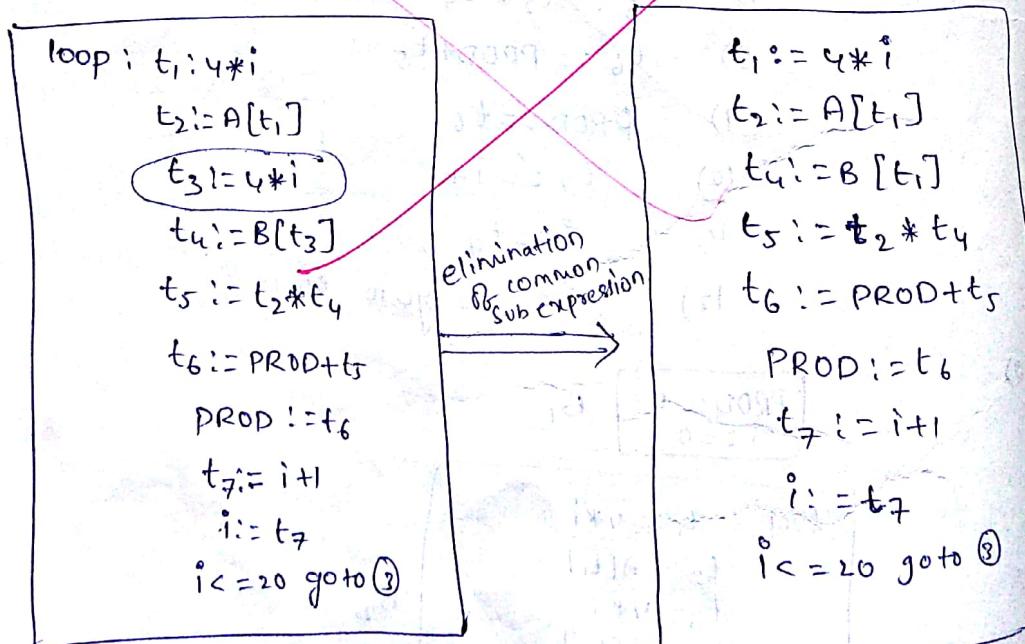

B<sub>2</sub>

### 3) Flow graph

### 4) elimination common sub expressions

From basic block  $B_2$ ,  $t_1$  and  $t_3$  are common terms  
i.e.,  $t_1 = t_3$  so that we can eliminate  $t_3$  i.e.,  $t_3 = 4*i$ ,  
we get

Data flow equation :-

Data flow equations are the equations representing the expressions that are appearing in the flow graph. These equations are useful for computing live variable and reaching definition.

→ Data flow equations can be computed by using forward (or) backward substitutions.

#### ♦ Representing data flow information :-

The data flow information can be represented by either set of properties (or) using bit vector with each bit representing a property.

Eg:-  $a := b + c$

$d := c * d$

$e := a - c$

$f := d + e$

The set of properties for the statements can be represented

1	1	0	1
$b+c$	$c*d$	$a-c$	$d+e$

here

$$a := b + c := 1 + 1 = 1$$

$$d := c * d := 1 * 1 = 1$$

$$e := a - c := 1 - 1 = 0$$

$$f := d + e := 1 + 1 = 1$$

Therefore  $[b+c, c*d, d+e]$

#### ♦ Data flow equations for programming construct :-

The data flow equation written as

$$\text{out}[s] = \text{gen}[s] \cup [\text{in}[s] - \text{kill}[s]]$$

where  $\rightarrow "s"$  = statement for which data flow equation can be written.

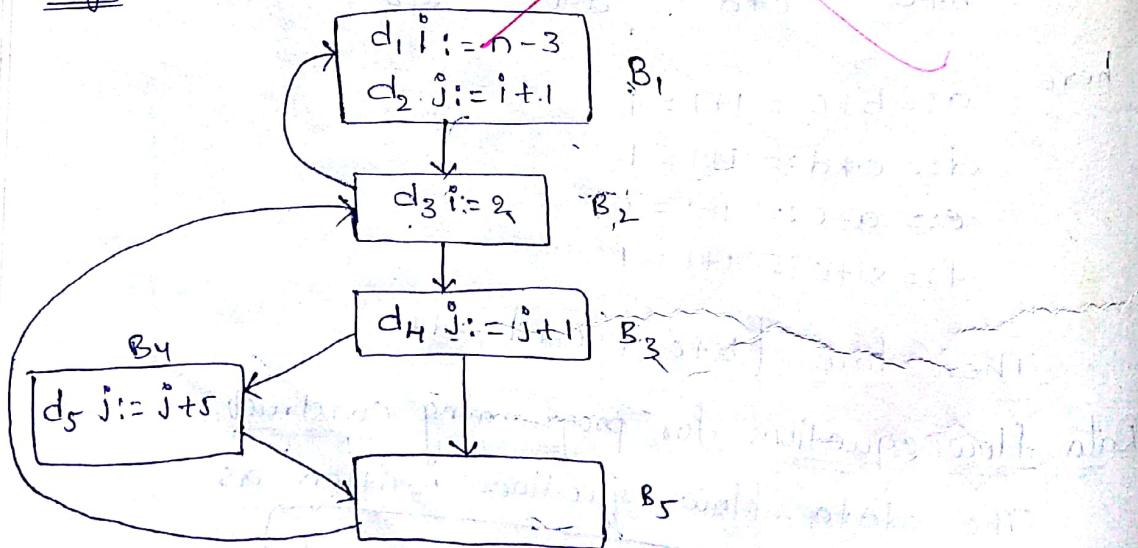

- "out" represents an output i.e., the information generated at the end of statement.
- "gen" represents the information generated within the Statement.
- "in" represents gathering information before entering in the loop.
- "kill" represents the information which is killed with in the control flow.

### ⇒ Reaching definition :-

In this section we will discuss how to obtain the solution to data flow equation using simple and efficient iterative algorithm by using this algorithm the computation of

$\text{gen}[B]$ ,  
 $\text{kill}[B]$ ,  
 $\text{in}[B]$ ,  
 $\text{out}[B]$ , is done.

Eg:-

Block	$\text{gen}[B]$	$\text{kill}[B]$
$B_1$	$\text{gen}[B_1] = \{d_1, d_2\}$ = $\{11000\}$	$\text{kill}[B_1] = \{d_3, d_4, d_5\}$ = $\{00111\}$
$B_2$	$\text{gen}[B_2] = \{d_3\}$ = $\{00100\}$	$\text{kill}[B_2] = \{d_1\}$ = $\{10000\}$
$B_3$	$\text{gen}[B_3] = \{d_4\}$ = $\{00010\}$	$\text{kill}[B_3] = \{d_2, d_5\}$ = $\{01001\}$
$B_4$	$\text{gen}[B_4] = \{d_5\}$ = $\{00001\}$	$\text{kill}[B_4] = \{d_2, d_4\}$ = $\{01010\}$
$B_5$	$\text{gen}[B_5] = \{\phi\}$ = $\{00000\}$	$\text{kill}[B_5] = \{\phi\}$ = $\{00000\}$

According to data flow equation we initialize  
 $\text{in}[B] = \phi$ ,  $\text{out}[B] = \text{gen}[B]$  for all basic blocks  
we get,

Initialization		
Block	$\text{in}[B]$	$\text{out}[B]$
$B_1$	0 0 0 0 0	{11000}
$B_2$	0 0 0 0 0	{00100}
$B_3$	0 0 0 0 0	{00010}
$B_4$	0 0 0 0 0	{00001}
$B_5$	0 0 0 0 0	{00000}

From the flow graph predecessor of  $B_1$  is  $B_2$

$$\therefore \text{in}[B_1] = \text{out}[B_2]$$

$$= \{00100\}$$

$$\text{out}[B_1] = \text{gen}[B_1] \cup (\{\text{in}[B_1] - \text{kill}[B_1]\})$$

$$= 11000 \cup (\{00100\} - \{00111\})$$

$$= 11000 \cup (00000)$$

$$\text{out}[B_1] = \{11000\}$$

Now consider block  $B_2$

$$\text{in}[B_2] = \text{out}[B_1] + \text{out}[B_5]$$

$$= 11000 + 00000$$

$$= \{11000\}$$

$$\text{out}[B_2] = \text{gen}[B_2] \cup (\{\text{in}[B_2] - \text{kill}[B_2]\})$$

$$= 00100 \cup (\{11000 - 10000\})$$

$$= 00100 \cup (01000)$$

$$\text{out}[B_2] = \{01100\}$$

consider block  $B_3$

$$\text{in}[B_3] = \text{out}[B_2]$$

$$= \{01100\}$$

$$\text{out}[B_3] = \text{gen}[B_3] \cup (\{\text{in}[B_3] - \text{kill}[B_3]\})$$

$$= 00010 \cup (01100 - 01001)$$

$$= 00010 \cup 00100$$

$$\text{out}[B_3] = \{00110\}$$

$$\text{similar } \text{in}[B_4] = \text{out}[B_3]$$

$$= \{00110\}$$

$$\text{out}[B_4] = \text{gen}[B_4] \cup (\{\text{in}[B_4] - \text{kill}[B_4]\})$$

$$= 00001 \cup (00100 - 01010)$$

$$= 100001 \cup 0010000110$$

$$\text{out}[B_4] = \{00101\}$$

Similarly

$$\text{in}[B_5] = \text{out}[B_3] + \text{out}[B_4]$$

$$= 00110 + 00101$$

$$= 00111$$

$$\text{out}[B_5] = \text{gen}[B_5] \cup (\{\text{in}[B_5] - \text{kill}[B_5]\})$$

$$= \{00000\} \cup (00111 - 00000)$$

$$= 00000 \cup 00111$$

$$\text{out}[B_5] = \{00111\}$$

Then the next two iterations can be computed in this way as we are considering this while loop will execute more than one.

PASS 1		
BLOCK	in[B]	out[B]
B <sub>1</sub>	{00100}	{11000}
B <sub>2</sub>	{11000}	{01100}
B <sub>3</sub>	{01100}	{00110}
B <sub>4</sub>	{00110}	{00101}
B <sub>5</sub>	{00111}	{00111}

Similarly pass 2, pass 3 can be calculated in above fashion.

PASS 2		
Block	In[B]	out[B]
B <sub>1</sub>	01100	11000
B <sub>2</sub>	11111	01111
B <sub>3</sub>	01111	00110
B <sub>4</sub>	00110	00101
B <sub>5</sub>	00111	00111

PASS 3		
Block	In[B]	Out[B]
B <sub>1</sub>	01111	11000
B <sub>2</sub>	11111	01111
B <sub>3</sub>	01111	00110
B <sub>4</sub>	00110	00101
B <sub>5</sub>	00111	00111

After pass 3 same iterations are coming for In[B] and out[B] hence pass 3 is final iteration.

### Live Variable Analysis:

Live variable is a variable it is used to further after its declaration. Before understanding how to compute data flow equations we will learn two important terms i.e.,

- i) use[s] = is a set of variables used by 's'
- ii) def [s] = is a set of variable defined by 's'

Eg:-

$$x := y + z$$

Here use = y, z

def = x

Eg:-

$$x := x + 1$$

Here use = x

def = x

Let us see an algorithm for computing an  
data flow equations using Live variable Analysis.

For all  $i$ ,  $in[i] = \emptyset$  and  $out[i] = \emptyset$

repeat until no change

for all  $i$

$$out[i] = \bigcup_{i' \in succ[i]} in[i']$$

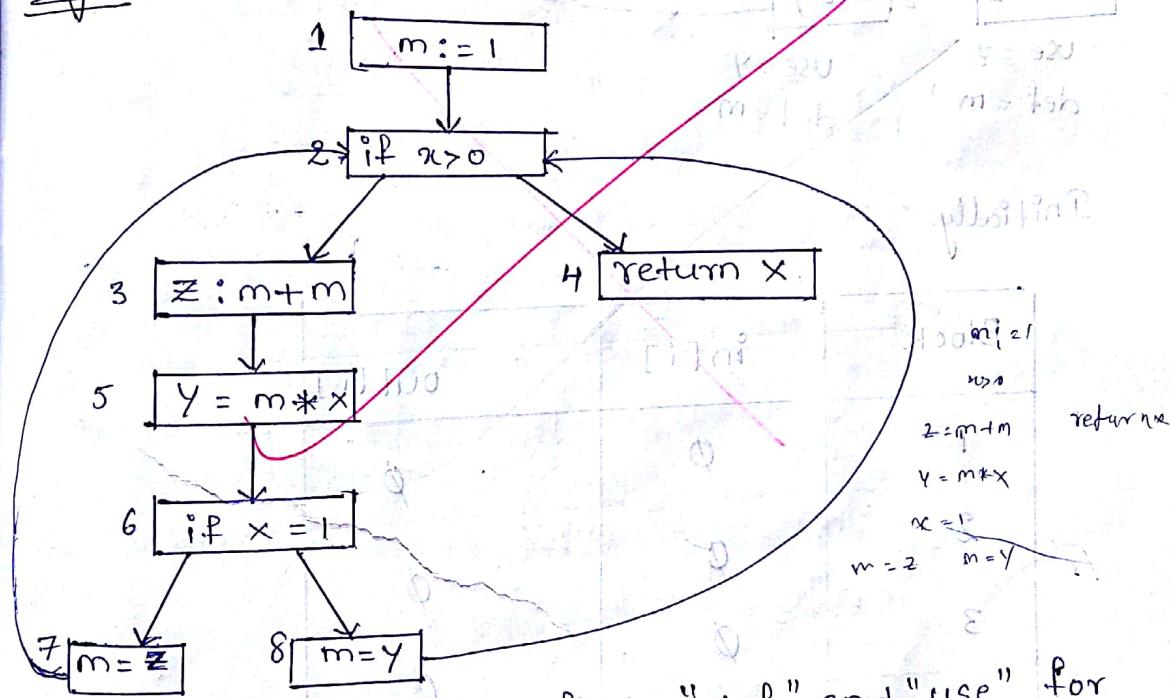

$$= i' \in succ[i]$$

$$in[i] = use[i] \cup [out[i] - def[i]]$$

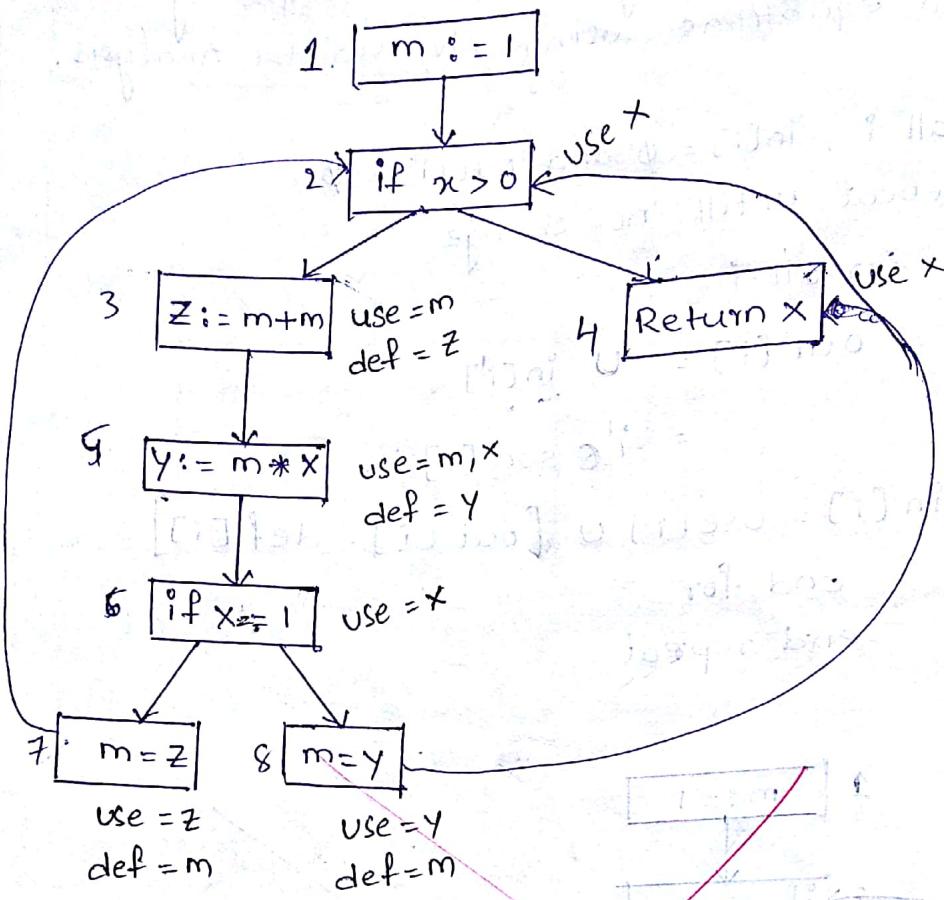

end for

end repeat

Eg:-

At first we will find "def" and "use" for each block in the given above flow graph.

Initially

Block	$in[i]$	$out[i]$
1	$\emptyset$	$\emptyset$
2	$\emptyset$	$\emptyset$
3	$\emptyset$	$\emptyset$
4	$\emptyset$	$\emptyset$
5	$\emptyset$	$\emptyset$
6	$\emptyset$	$\emptyset$
7	$\emptyset$	$\emptyset$
8	$\emptyset$	$\emptyset$

Now we compute  $\text{out}[i] = \cup \text{in}[i']$  where ' $i'$ ' is successor node of ' $i$ '.

$$\text{in}[i] = \text{use}[i] \cup [\text{out}[i] - \text{def}[i]]$$

$$\text{out}[2] = \text{in}[3] \cup \text{in}[4]$$

$$= \emptyset \cup \emptyset$$

$$\boxed{\text{out}[2] = \emptyset}$$

$$\text{in}[2] = \text{use}[2] \cup [\text{out}[2] - \text{def}[2]]$$

$$= \times \cup [\emptyset - \emptyset]$$

$$\boxed{\text{in}[2] = \times}$$

$$\text{out}[3] = \text{in}[5] - \times$$

$$\boxed{\text{out}[3] = \emptyset}$$

$$\text{in}[3] = \text{use}[3] \cup [\text{out}[3] - \text{def}[3]]$$

$$= m \cup [\emptyset - z]$$

$$\boxed{\text{in}[3] = m}$$

Since complement  $z$  can be eliminated

$$\boxed{\text{out}[4] = \emptyset}$$

$$\text{in}[4] = \text{use}[4] \cup [\text{out}[4] - \text{def}[4]]$$

$$\cancel{\text{top row}} \quad \cancel{x} \cup [\emptyset - \emptyset]$$

$$\boxed{\text{in}[4] = \times}$$

$$\text{out}[5] = \text{in}[6]$$

$$\boxed{\text{out}[5] = \emptyset}$$

$$\text{in}[5] = \text{use}[5] \cup [\text{out}[5] - \text{def}[5]]$$

$$= (m, x) \cup [\emptyset - y]$$

$$\boxed{\text{in}[5] = m, x}$$

$$\text{out}[6] = \text{in}[7] \cup \text{in}[8]$$

$$= \emptyset \cup \emptyset$$

$$\boxed{\text{out}[6] = \emptyset}$$

$$\text{in}[6] = \text{use}[6] \cup [\text{out}[6] - \text{def}[6]]$$

$$= \times \cup [\emptyset - \emptyset]$$

$$\boxed{\text{in}[6] = \times}$$

$$\text{out}[7] = \text{in}[2]$$

$$\boxed{\text{out}[7] = \times}$$

$$\text{in}[7] = \text{use}[7] \cup [\text{out}[7] - \text{def}[7]]$$

$$= z \cup [\times - m]$$

$$\boxed{\text{in}[7] = x, z}$$

$$\text{out}[8] = \text{in}[4]$$

$$\boxed{\text{out}[8] = \times}$$

$$\text{in}[8] = \text{use}[8] \cup [\text{out}[8] - \text{def}[8]]$$

$$= y \cup [x - m]$$

$$\boxed{\text{in}[8] = y, x}$$

After 1<sup>st</sup> pass we get

block	$\text{in}[i]$	$\text{out}[i]$
1	$\emptyset$	$\emptyset$
2	$x$	$\emptyset$
3	$m$	$\emptyset$
4	$x$	$\emptyset$
5	$m, x$	$\emptyset$
6	$x$	$y - \emptyset$
7	$x, z$	$x$
8	$x, y$	$x$

Now we computed for pass 2

$$\text{out}[1] = \text{in}[2]$$
$$= x$$

$$\text{b} \quad \text{in}[1] = \text{use}[1] \cup [\text{out}[1] - \text{def}[1]]$$
$$= \emptyset \cup [x - \emptyset]$$
$$= x$$

$$\text{out}[2] = \text{in}[3] \cup \text{in}[4]$$
$$= m \cup x$$
$$= m, x$$

$$\text{in}[2] = \text{use}[2] \cup [\text{out}[2] - \text{def}[2]]$$
$$= x \cup [m, x - \emptyset]$$
$$= x, m$$

$$\text{out}[3] = \text{in}[5]$$

$$= m, x$$

~~$$\text{in}[3] = \text{use}[3] \cup [\text{out}[3] - \text{def}[3]]$$
$$= m \cup [m, x - z]$$
$$= m, x$$~~

~~$$\text{out}[4] = \emptyset$$~~

$$\text{in}[4] = \text{use}[4] \cup [\text{out}[4] - \text{def}[4]]$$
$$= x \cup [\emptyset - \emptyset]$$
$$= x$$

~~$$\text{out}[5] = \text{in}[6]$$~~

~~$$= x$$~~

Since  $\text{in}[4] \neq \text{out}[4]$   
is same as pass 1  
Hence we will not  
consider  $\text{in}[4] \neq \text{out}[4]$   
again.

$$\text{in}[5] = \text{use}[5] \cup [\text{out}[5] - \text{def}[5]]$$
$$= m, x \cup [x - y]$$
$$= m, x$$

$$\text{out}[6] = \text{in}[7] \cup \text{in}[8]$$

$$= x, z \cup x, y$$

$$= x, y, z$$

$$\text{in}[6] = \text{use}[6] \cup [\text{out}[6] - \text{def}[6]]$$

$$= x \cup [x, y, z - \emptyset]$$

$$= x, y, z$$

$$\text{out}[7] = \text{in}[2]$$

$$= x, m$$

$$\text{in}[7] = \text{use}[7] \cup [\text{out}[7] - \text{def}[7]]$$

$$= z \cup [m, x - m]$$

$$= x, z$$

$$\text{out}[8] = \text{in}[2]$$

$$= x, m$$

$$\text{in}[8] = \text{use}[8] \cup [\text{out}[8] - \text{def}[8]]$$

$$= y \cup [x, m - m]$$

$$\text{PASS 2} = x, y$$

	$\text{in}[i]$	$\text{out}[i]$
1.	x	$(x - x) \cup \emptyset$
2.	$x, m$	$x, m$
3.	$x, m$	$x, m$
4.	x	$\emptyset$
5.	$x, m$	x
6.	$x, y, z$	$x, y, z$
7.	$x, z$	$x, m$
8.	$x, y$	$m, x$

PASS 3

$$\text{out}[1] = \text{in}[2]$$
$$= x, m$$

$$\text{in}[1] = \text{use}[1] \cup [\text{out}[1] - \text{def}[1]]$$
$$= \emptyset \cup [x, m - m]$$
$$= x$$

$$\text{out}[2] = \text{in}[3] \cup \text{in}[4]$$

$$= x, m \cup x$$
$$= x, m$$

$$\text{in}[2] = \text{use}[2] \cup [\text{out}[2] - \text{def}[2]]$$
$$= (\emptyset \cup [x, m - \emptyset]) \cup [x, m - x]$$
$$= [x, m - x] \cup \emptyset$$

$$\text{out}[3] = \text{in}[5]$$

~~$$\text{in}[3] = \text{use}[3] \cup [\text{out}[3] - \text{def}[3]]$$
$$= m \cup [m, x - z]$$
$$= x, m$$~~

~~$$\text{out}[4] = \emptyset$$~~

~~$$\text{in}[4] = \text{use}[4] \cup [\text{out}[4] - \text{def}[4]]$$
$$= x \cup [\emptyset - \emptyset]$$
$$= x$$~~

$$\text{out}[5] = \text{in}[6]$$

$$= x, y, z$$

~~$$\text{in}[5] = \text{use}[5] \cup [\text{out}[5] - \text{def}[5]]$$
$$= x \cup [x, y, z - y]$$
$$= x, z$$~~

$$\begin{aligned} \text{out}[6] &= \text{in}[7] \cup \text{in}[8] \\ &= x, z \cup x, y \\ &= x, y, z \end{aligned}$$

$$\text{in}[6] = \text{use}[6] \cup [\text{out}[6] - \text{def}[6]]$$

$$= x \cup [x, y, z - \emptyset]$$

$$= x, y, z$$

$$\text{out}[7] \leq \text{in}[2]$$

$$= x, m$$

$$\text{in}[7] = \text{use}[7] \cup [\text{out}[7] - \text{def}[7]]$$

$$= z \cup [x, m - m]$$

$$= x, z$$

~~out[8], in[8] is same as pass 2~~

Pass 3

1.	x	m, x
5.	m, y, z	x, y, z

~~Remaining all are same~~

We will compute pass 4 we get only one changed value

$$\text{out}[3] = \text{in}[5]$$

$$m, x, z$$

$$\text{in}[3] = \text{use}[3] \cup [\text{out}[3] - \text{def}[3]]$$

$$= m \cup [m, x, z - z]$$

$$= m, x$$

$\text{in}[1]$  and  $\text{in}[5]$  are similar to that of previous pass. After pass 4 we get.

3.	$m, x, z$	$m, x, z$
----	-----------	-----------

After this pass we get same values as previous then stop the procedure we get.

Block	in[i]	out[i]
1.	$x$	$m, x$
2.	$m, x$	$m, x$
3. main	$m, x$	$m, x, z$
4.	$x$	$\emptyset$
5.	$m, x, z$	$x, y, z$
6.	$x, y, z$	$x, y, z$
7.	$m, x$	$x, z$
8.	$x, y$	$m, x$

### Global Optimization :-

~~Local optimization :-~~ The local optimization can optimize the code with in the basic block whereas in global optimization we can optimize the code out of the basic block & with in the basic block.

In global optimization we implement two

types of analysis

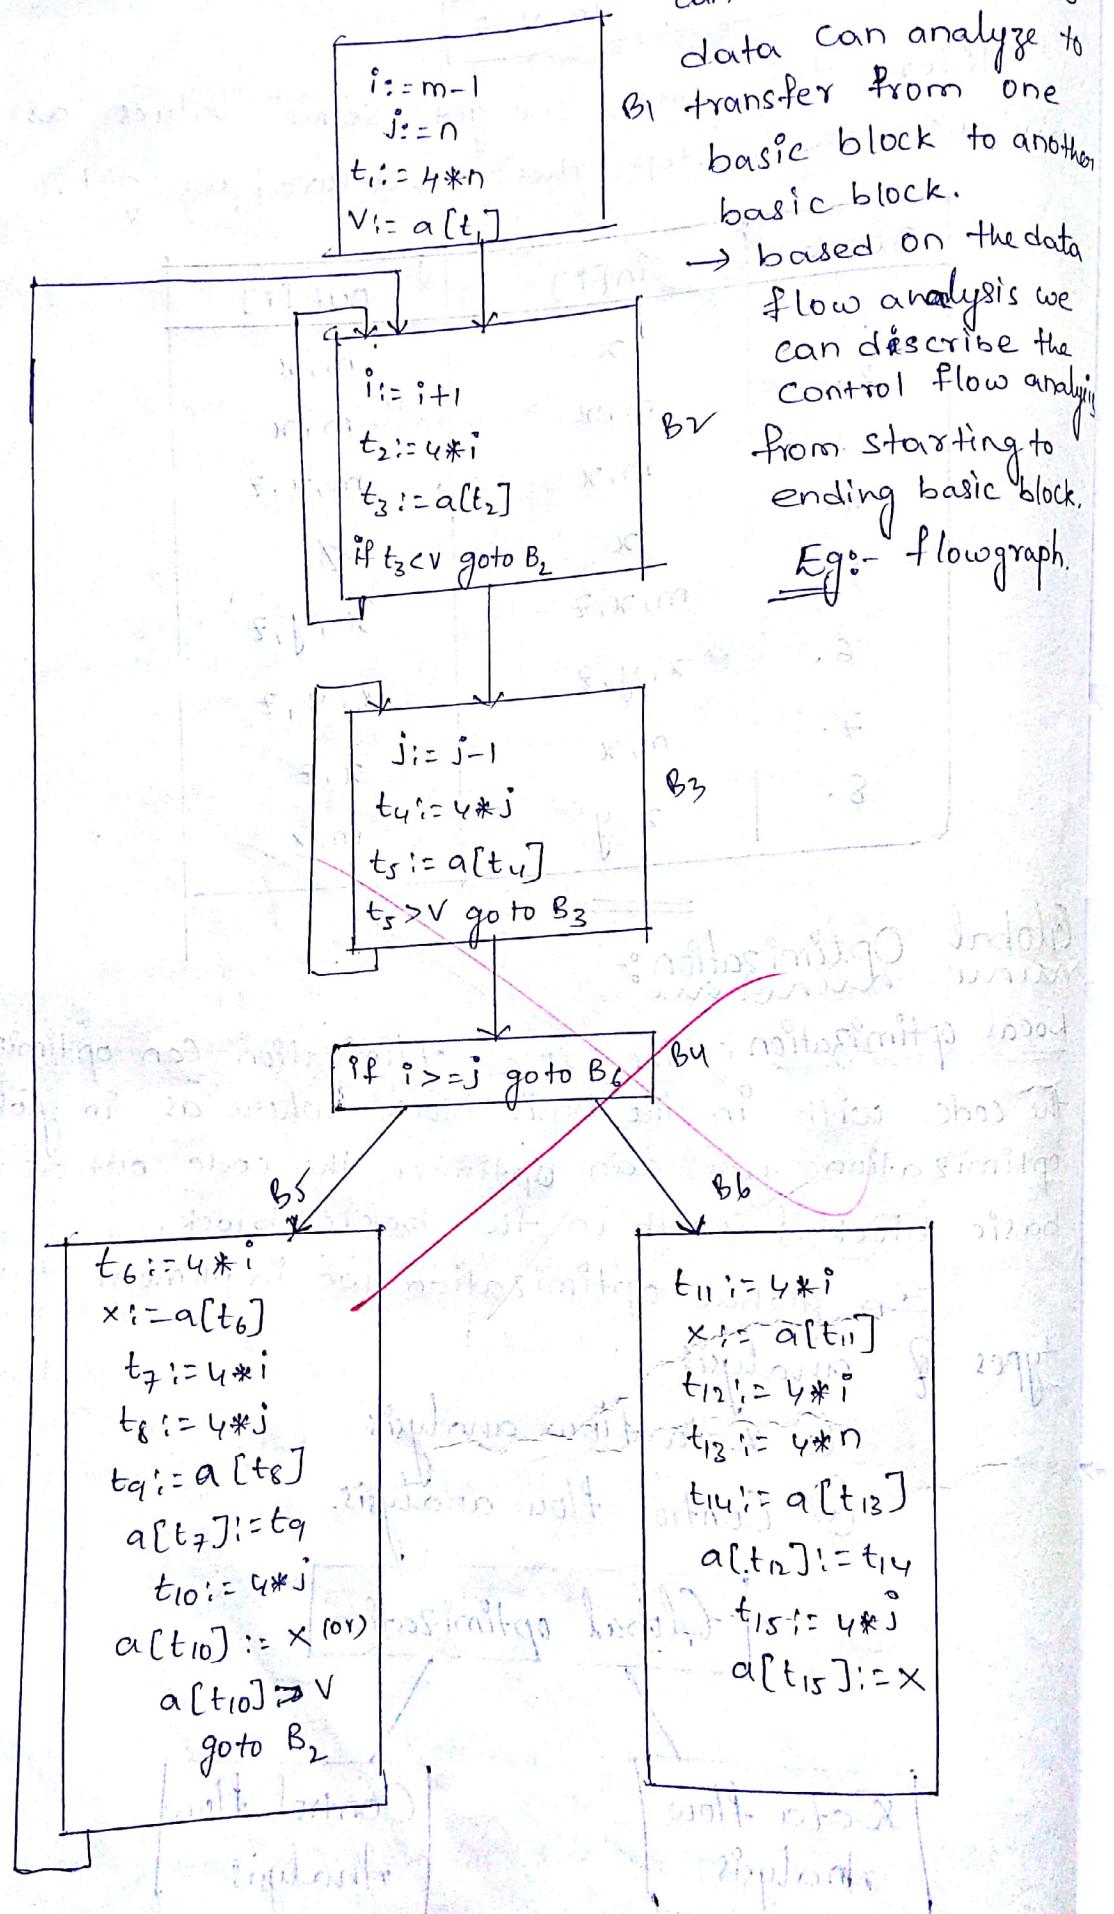

① Data flow analysis

② Control flow analysis.

Global optimization

Data flow  
Analysis

Control flow  
Analysis

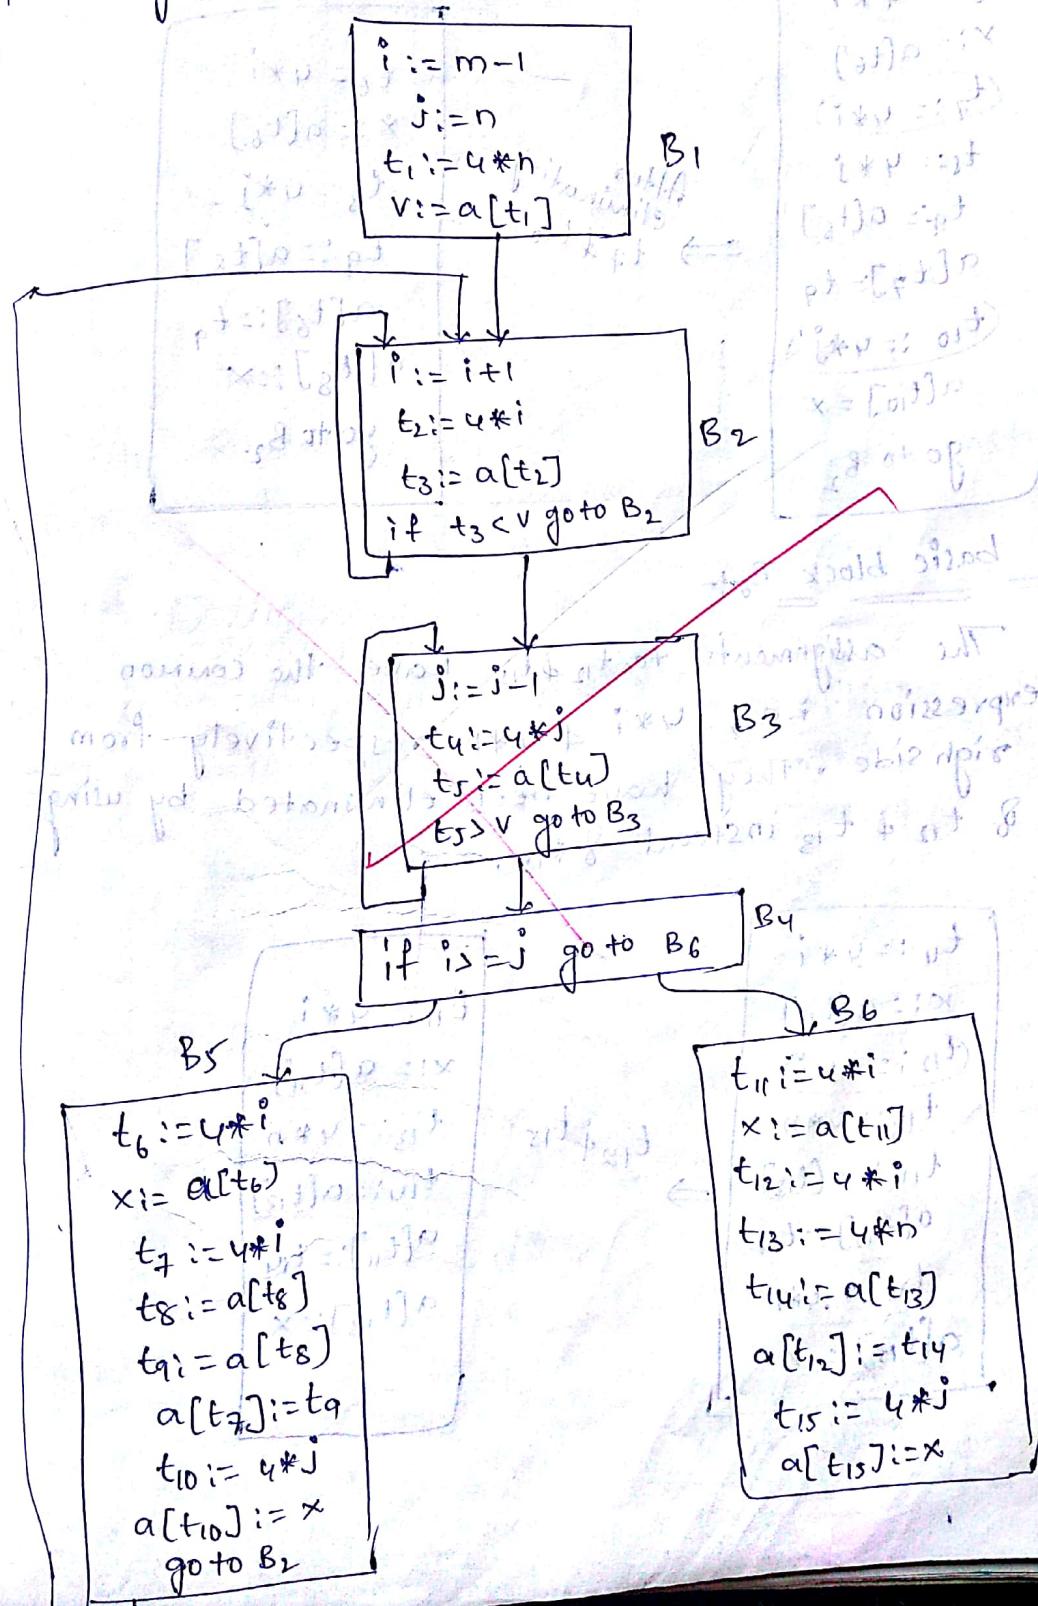

→ In data flow analysis, we can describe how data can analyze to transfer from one basic block to another basic block.

→ based on the data flow analysis we can describe the control flow analysis from starting to ending basic block.  
Eg:- flowgraph.

## Redundant Common Sub expression elimination

An occurrence of an expression 'E' is called a common subexpression, if 'E' was previously computed and the values of variables in 'E' have not changed since the previous computation. we can avoid recomputing the expression if we can use the previously computed value for example

From the basic block  $B_5$

The assignments

Sub expression i.e.,  $4 * i$  right side. They have  $t$  instead of  $t_1$  and  $t_8$  in.

$$t_6 := 4 * i$$

$$x := a[t_6]$$

$$\textcircled{t_7 := 4 * i}$$

$$t_8 := 4 * j$$

$$t_9 := a[t_8]$$

$$a[t_7] = t_9$$

$$\textcircled{t_{10} := 4 * j}$$

$$a[t_{10}] = x$$

go to  $B_2$

After  
eli  
 $\Rightarrow t$

from basic block  $B_6$  :-

After local common sub expressions are eliminated  
 B<sub>5</sub> still evaluate  $4*i$  and  $4*j$ , they have been eliminated  
 by using  $t_2$  instead of  $t_6$  and  $t_8$  instead of  $t_8$   
 after eliminating  $t_6$  and  $t_8$  the basic block B<sub>5</sub> can  
 be written as.

$t_6 := 4*i$   
 $x := a[t_6]$   
 $t_8 := 4*j$   
 $t_9 := a[t_8]$   
 $a[t_6] := t_9$   
 $a[t_8] := x$   
 go to B<sub>2</sub>

$x := a[t_2]$   
 $t_9 := a[t_4]$   
 $a[t_2] = t_9$   
 $a[t_4] = x$   
 go to B<sub>2</sub>

The common sub expression  $t_{11}$  &  $t_{13}$  have been  
 eliminated by using  $t_2$  instead of  $t_{11}$  &  $t_{13}$  instead  
 of  $t_{13}$

$t_{11} := 4*i$   
 $x := a[t_{11}]$   
 ~~$t_{13} := 4*i$~~   
 $t_{14} := a[t_{13}]$   
 $a[t_{11}] := t_{14}$   
 $a[t_{13}] := x$

$x := a[t_2]$   
 $t_{14} := a[t_1]$   
 $a[t_2] = t_{14}$   
 $a[t_1] = x$

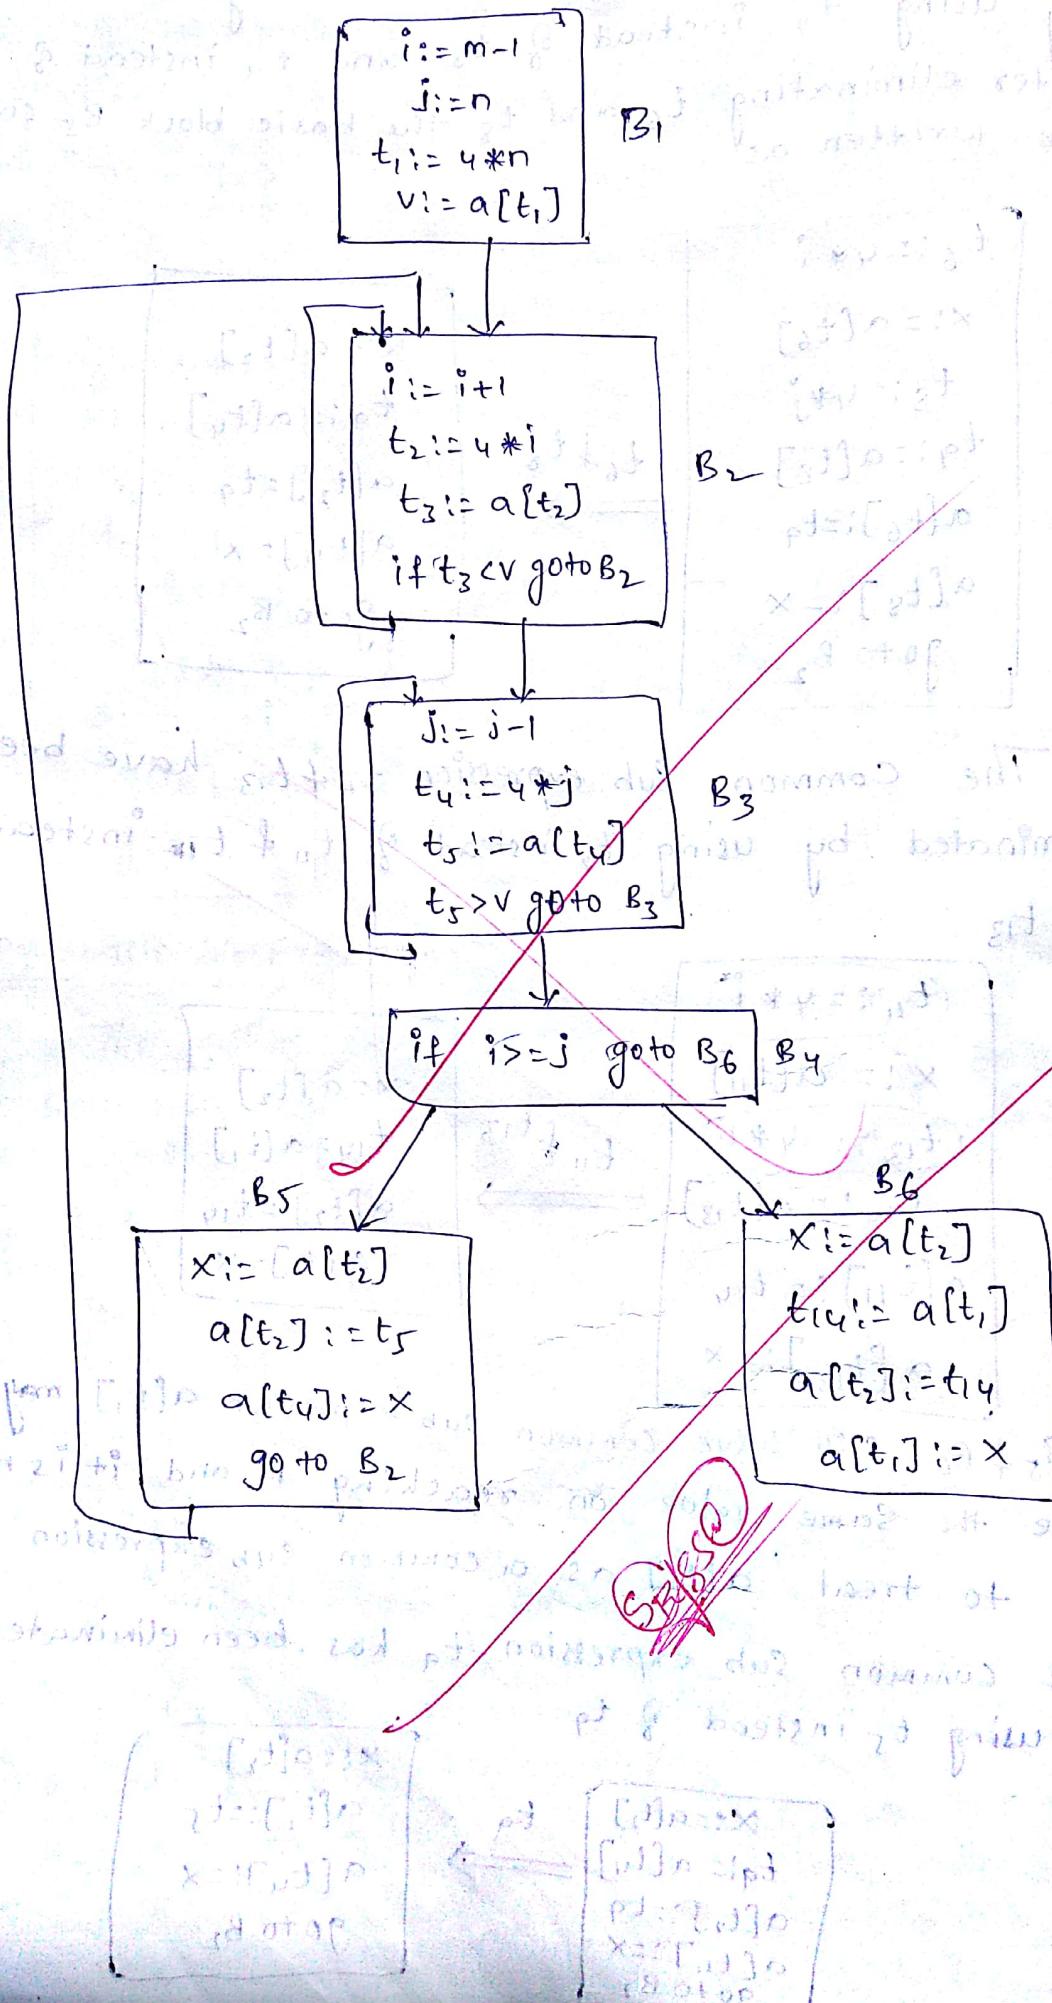

B<sub>5</sub> & B<sub>6</sub> still have common sub expression  $a[t_1]$  may not  
 have the same value on reaching B<sub>6</sub> and it is not  
 safe to treat  $a[t_1]$  as a common sub expression  
 → The common sub expression  $t_9$  has been eliminated  
 by using  $t_5$  instead of  $t_9$

$x := a[t_2]$   
 $t_9 := a[t_4]$   
 $a[t_2] := t_9$   
 $a[t_4] := x$   
 go to B<sub>2</sub>

$x := a[t_2]$   
 $a[t_2] := t_5$   
 $a[t_4] := x$   
 go to B<sub>2</sub>

The flow graph after common sub expression elimination

are eliminated:

12/10/2014

## UNIT - 8

### Object Code Generation

- object code forms
- Machine dependent code optimization
- Register allocation & assignment, generic code generation algorithm
- DAG for register allocation.

Introduction to code generation:

The final phase of compiler is code generation. It takes intermediate code representation of the source program as the input and produces a target program (or) object program as its output.

The semantic representation as shown in bellow.

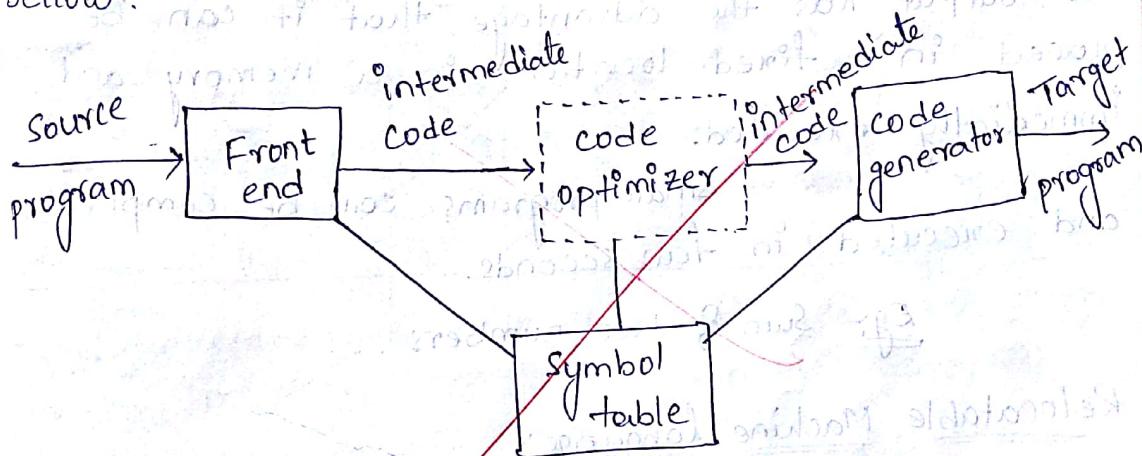

Fig:- position of code generation.

In the above diagram we mainly concentrate on front end and back end.

\* Here source program act as front end and target program act as back end.

\* In source program we are using different types of programming languages like C, C++, Java, PHP, .Net, C#, HTML, CSS, SOAP, JSON, DHTML, XML...

COBOL, PASCAL, Ada, Perl, Python.

- \* In target program nothing but backend here we are using different types of databases like MySQL, Oracle 9i, Oracle 10g, SQL, XAMPP, WAMP, LAMP, SQL, Yogo.

Object code forms:

The output of the code generator is target program (or) object program. The object program may takes for many forms such as

1. Absolute machine language
2. relocatable machine language
3. Assembly language

Absolute machine language:-

producing the absolute machine language as output has the advantage that it can be placed in a fixed location in a memory and immediately executed.

Small programs can be compiled and executed in few seconds.

Eg:- Sum of two numbers ...

Relocatable Machine language:

producing the relocatable machine language as output allows sub programs. And all this sub programs to be compiled separately.

- It provides flexibility to compile sub routines separately and to call previously compiled programs from an object module.
- If the target machine does not handle relocation automatically.

## Assembly language:-

- producing an assembly language program as output makes the process of code generation. In this assembly language we use symbolic instructions and macro facilities of the assembler and to generate the target code.
- Assembly language nothing but machine level language it generates the binary numbers 0 & 1.
  - The advantage for this machine is small memory where compiler must use several passes.
  - The main intention of assembly language is producing high level language as output simplifies code generation even further.

## Machine dependent code generation and generic code generation algorithm:-

### Machine dependent code generation:-

Any compiler (or) programmer can convert the source program into target program. Target program nothing but machine level language. In machine dependent code generation we are using intermediate code representation as input and target program as output.

target program as output. After compilation of target program it generates binary numbers i.e., 0's & 1's.

In this we implement micro processor commands and their registers.

Eg:- MOV : it is used to move source to destination.

ADD : it is used to Add source to destination.

MUL : it is used to Multiply source to destination.

SUB : it is used to Subtract source from destination.

- The source and destination fields are not long enough to hold memory address, so certain bit patterns in this field specify that following an instruction contain operands and address.
- Source & destination of an instruction are specified by combining registers and memory locations with address mode.
- The address modes together with their assembly language forms and associated cost are as shown in below table.

Mode	Form	Address	Address cost.
Absolute	M	M	1
Register indexed	R	R	0
Indirect register	C(R)	c + contents(R)	1
Indirect indexed	*R	contents(R)	0
Literal	#C(R)	contents(c + contents(R))	1
		Source to be a constant	1

Eg: 1. ~~MOV R0, M~~; store the contents of register 'R0' into memory location 'M'

2. ~~MOV A(R0), M~~; Stores the value contents (A + contents of R0) into memory location of M

3. ~~MOV \*A(R0), M~~; Stores the value contents (contents A + contents (R0)) into the memory location of M

4. ~~MOV \$1, R0~~; Loads the constant 1 into register R0

Instruction Cost :- The cost of an instruction to be one plus the cost associated with source and destination address modes. This cost corresponds to length of instructions.

For the most machines and for the most machine instructions, the time taken to fetch an instruction from memory and we implement 3-address code statement that is  $a = b + c$ .

This statement can be implemented by many different instruction they are.

	1t address mode cost	Instruction cost
1) MOV b, R <sub>0</sub>	1+1	2
2) ADD C, R <sub>0</sub>	1+1	2
3) MOV R <sub>0</sub> , a	1+1	2
Total cost is		6

Generic Code generation algorithm :-

Write generate code for the following expression

$$x := (a+b) * (c-d) + ((e+f) * (a+b))$$

~~Solution First write the 3 address code statement for above expression.~~

$$t_1 := a + b$$

$$t_2 := c - d$$

$$t_3 := e / f$$

$$t_4 := t_1 * t_2$$

$$t_5 := t_3 * t_1$$

$$t_6 := t_4 + t_5$$

using code generation algorithm the sequence target code can be generated as shown in below.

Three address code	Target code Sequence	Register descriptor(R)	operand descriptor.
$t_1 := a + b$	MOV a, R <sub>0</sub> Add b, R <sub>0</sub>	Empty R <sub>0</sub> contain t <sub>1</sub>	$t_1 \boxed{R} R_0$
$t_2 := c - d$	MOV c, R <sub>1</sub> Sub d, R <sub>1</sub>	R <sub>1</sub> contain C R <sub>1</sub> contain t <sub>2</sub>	$t_2 \boxed{R} R_1$
$t_3 := e / f$	Mov e, R <sub>2</sub> div f, R <sub>2</sub>	R <sub>2</sub> contain e R <sub>2</sub> contain t <sub>3</sub>	$t_3 \boxed{R} R_2$
$t_4 := t_1 * t_2$	MUL R <sub>0</sub> , R <sub>1</sub>	R <sub>0</sub> contain t <sub>1</sub> R <sub>1</sub> contain t <sub>2</sub> R <sub>1</sub> contain t <sub>4</sub>	$t_4 \boxed{R} R_1$
$t_5 := t_3 * t_1$	MUL R <sub>2</sub> , R <sub>0</sub>	R <sub>2</sub> contain t <sub>3</sub> R <sub>0</sub> contain t <sub>1</sub> R <sub>0</sub> contain t <sub>5</sub>	$t_5 \boxed{R} R_0$
$t_6 := t_4 + t_5$	Add R <sub>1</sub> , R <sub>0</sub>	R <sub>1</sub> contain t <sub>4</sub> R <sub>0</sub> contains t <sub>5</sub> R <sub>0</sub> contain t <sub>6</sub>	$t_6 \boxed{R} R_0$

~~Generate the code sequence using code generation algorithm for the following expression.~~

$$w := (A - B) + (A - C) + (A - C)$$

Sol:-

3-address code for the given expression

$$t_1 := A - B$$

$$t_2 := A - C$$

$$t_3 := t_1 + t_2$$

$$t_4 := t_3 + t_2$$

$$w := t_4$$

Three address code

Targetcode sequence

register descriptor

operand descriptor

$t_1 := A - B$

Mov A, R<sub>0</sub>  
Sub B, R<sub>0</sub>

Empty  
R<sub>0</sub> contain t<sub>1</sub>

t <sub>1</sub>	R	R <sub>0</sub>
----------------	---	----------------

$t_2 := A - C$

Mov A, R<sub>1</sub>  
Sub C, R<sub>1</sub>

R<sub>1</sub> contain A  
R<sub>1</sub> contain t<sub>2</sub>

t <sub>2</sub>	R	R <sub>1</sub>
----------------	---	----------------

$t_3 := t_1 + t_2$

Add R<sub>0</sub>, R<sub>1</sub>

R<sub>0</sub> contain t<sub>1</sub>  
R<sub>1</sub> contain t<sub>2</sub>  
R<sub>1</sub> contain t<sub>3</sub>

t <sub>3</sub>	R	R <sub>1</sub>
----------------	---	----------------

$t_4 := t_3 + t_2$

Add R<sub>1</sub>, R<sub>1</sub>

R<sub>1</sub> contain t<sub>4</sub>

t <sub>4</sub>	R	R <sub>1</sub>
----------------	---	----------------

$W := t_4$

Mov R<sub>1</sub>, W

W contain t<sub>4</sub>

t <sub>4</sub>	R	R <sub>1</sub>
----------------	---	----------------

3) generate the code sequence using code generation algorithm for following expression.

$$P := ((x+y) + (z+w)) * ((a+b) + (c-d))$$

3-address code

$t_1 := x + y$

~~$t_2 := z + w$~~

$t_3 := a + b$

$t_4 := c - d$

$t_5 := t_1 + t_2$

$t_6 := t_3 + t_4$

$t_7 := t_5 * t_6$

~~$t_{sp} := t_7$~~

Three address code	Target code Sequence	Register descriptor	operand descriptor
$t_1 := x + y$	MOV x, R <sub>0</sub> add y, R <sub>0</sub>	Empty R <sub>0</sub> contain t <sub>1</sub>	t <sub>1</sub> R R <sub>0</sub>
$t_2 := z + w$	MOV z, R <sub>1</sub> add w, R <sub>1</sub>	R <sub>1</sub> contain z R <sub>1</sub> contain t <sub>2</sub>	t <sub>2</sub> R R <sub>1</sub>
$t_3 := a + b$	MOV a, R <sub>2</sub> add b, R <sub>2</sub>	R <sub>2</sub> contain a R <sub>2</sub> contain t <sub>3</sub>	t <sub>3</sub> R R <sub>2</sub>
$t_4 := c - d$	MOV c, R <sub>3</sub> SUB d, R <sub>3</sub>	R <sub>3</sub> contain c R <sub>3</sub> contain t <sub>4</sub>	t <sub>4</sub> R R <sub>3</sub>
$t_5 := t_1 + t_2$	add R <sub>0</sub> , R <sub>1</sub>	R <sub>0</sub> contain t <sub>1</sub> R <sub>1</sub> contain t <sub>2</sub>	t <sub>5</sub> R R <sub>1</sub>
$t_6 := t_3 + t_4$	add R <sub>2</sub> , R <sub>3</sub>	R <sub>2</sub> contain t <sub>3</sub> R <sub>3</sub> contain t <sub>4</sub>	t <sub>6</sub> R R <sub>3</sub>
$t_7 := t_5 * t_6$	add R <sub>1</sub> , R <sub>3</sub>	R <sub>1</sub> contains t <sub>5</sub> R <sub>3</sub> contain t <sub>6</sub> R <sub>3</sub> contain t <sub>7</sub>	t <sub>7</sub> R R <sub>3</sub>
P := t <sub>7</sub>	MOV P	P contain t <sub>7</sub>	

# Code generation using DAG :-

- 1) Compute DAG for following 3-address statement considering DAG as an example the process & explain the process of code generation (only 2 registers)

$$t_1 := a + b$$

$$t_2 := c + d$$

$$t_3 := e - t_2$$

$$t_4 := t_1 - t_3$$

Sol

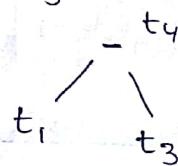

We will construct DAG for  $t_1 := a + b$

$$t_2 := c + d$$

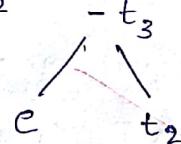

$$t_3 := e - t_2$$

$$t_4 := t_1 - t_3$$

$$t_4 = t_1 - t_3$$

$$t_3 = e - t_2$$

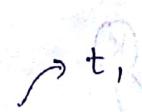

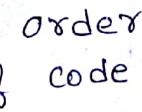

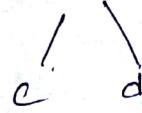

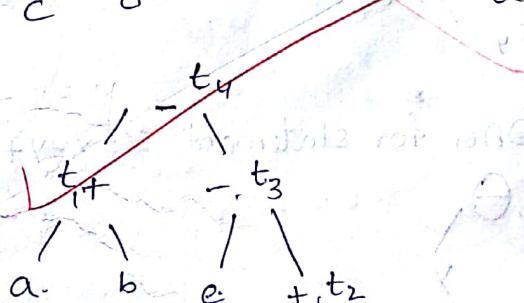

$$t_2 = c + d$$

$$t_1 := a + b$$

$$a + b$$

For the above generate generation of code shown in below.

```

MOV a, R0
ADD b, R0
MOV c, R1
ADD d, R1
  
```

MOV R<sub>0</sub>, #1

MOV e, R<sub>0</sub> → t<sub>3</sub>

Sub R<sub>1</sub>, R<sub>0</sub>

MOV t<sub>1</sub>, R<sub>1</sub>

Sub R<sub>0</sub>, R<sub>1</sub>

MOV R<sub>1</sub>, t<sub>4</sub>

Now we change the sequence of computation as.

t<sub>2</sub> = c + d

t<sub>3</sub> = e + t<sub>2</sub>

t<sub>1</sub> = a + b

t<sub>4</sub> = t<sub>1</sub> - t<sub>3</sub>

MOV c, R<sub>0</sub>

Add d, R<sub>0</sub> → t<sub>2</sub>

MOV e, R<sub>1</sub>

Sub R<sub>0</sub>, R<sub>1</sub> → t<sub>3</sub>

MOV a, R<sub>0</sub>

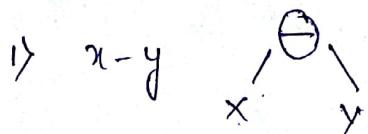

Add b, R<sub>0</sub> → t<sub>1</sub>

Sub R<sub>1</sub>, R<sub>0</sub>

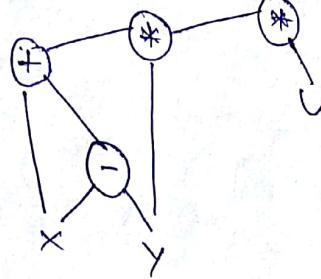

MOV R<sub>0</sub>, t<sub>4</sub>

Q) Show the DAG for statement  $Z = x - y + x * y * u - v / w * x * v$

Sol

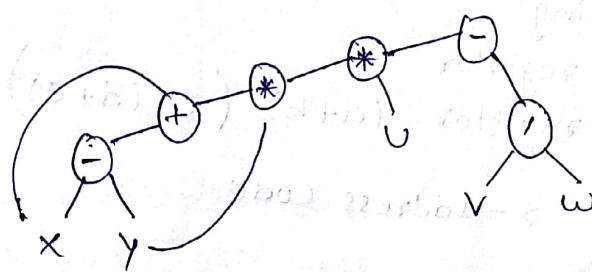

$$4) x - y + x * y * v$$

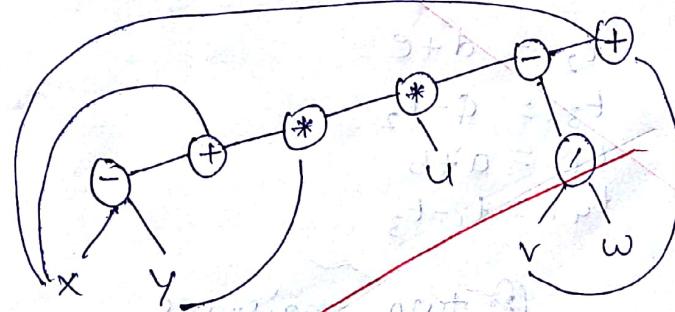

$$5) v/w$$

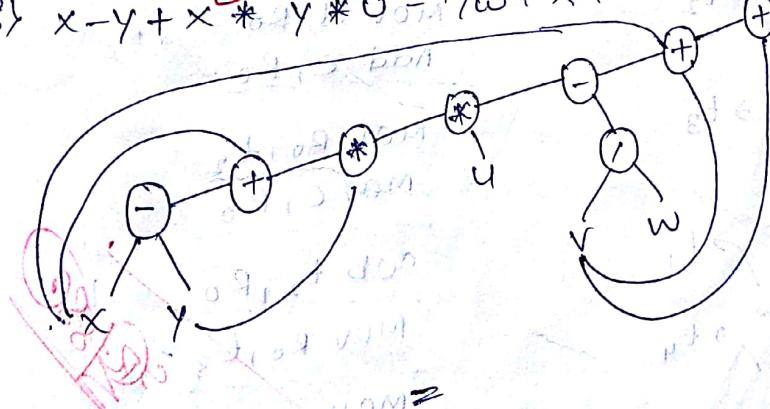

$$6) x - y + x * y * v - v/w$$

$$7) x - y + x * y * v - v/w + x$$

$$8) x - y + x * y * v - v/w + x + v$$

3) generate code for following statements  $a = b+c$   
 $d = a+e$   
(only 1 register)

Sol

Given  $a = b+c$   
 $d = a+e$

MOV b, R<sub>0</sub>

Add c, R<sub>0</sub>

MOV a, R<sub>0</sub>

Add e, R<sub>0</sub>

MOV R<sub>0</sub>, d

4) generate code for following expression obtain  
optimal code using

1) only 1 register  $(a+b)-(c-(d+e))$

2) only 2 registers

Sol

First we write 3-address code

$$t_1 = a+b$$

$$t_2 = d+e$$

$$t_3 = c-t_2$$

$$t_4 = t_1 - t_3$$

we change the sequence

~~$t_2 := d+e$~~

~~$t_3 := c-t_2$~~

~~$t_1 := a+b$~~

~~$t_4 := t_1 - t_3$~~

① One register

MOV d, R<sub>0</sub>  $\rightarrow t_2$

add e, R<sub>0</sub>

MOV c, R<sub>1</sub>  $\rightarrow t_3$

Sub R<sub>0</sub>, R<sub>1</sub>

MOV a, R<sub>0</sub>  $\rightarrow t_1$

Add b, R<sub>0</sub>

Sub R<sub>1</sub>, R<sub>0</sub>  $\rightarrow t_4$

② two registers

MOV d, R<sub>0</sub>  $\rightarrow t_2$

Add e, R<sub>0</sub>

MOV R<sub>0</sub>, t<sub>2</sub>

MOV c, R<sub>0</sub>

Sub t<sub>2</sub>, R<sub>0</sub>

MOV R<sub>0</sub>, t<sub>3</sub>

MOV a, R<sub>0</sub>  $\rightarrow t_1$

Add b, R<sub>0</sub>

Sub t<sub>3</sub>, R<sub>0</sub>  $\rightarrow t_4$

Register allocation and assignment :-

(50)

- \* Global Register Allocation
- \* Usage counts
- \* Register Assignment for outer loops
- \* Register Allocation by graph coloring
